Accumulation and Incorporation of Amino-acid in Rat Intestine *in vitro*

INVESTIGATIONS of the absorption of amino-acids from the intestinal tract have usually been concerned with a single amino-acid or, in some cases, simple mixtures of a few amino-acids¹⁻³. Under physiological conditions, on the other hand, an initial stage in the assimilation of dietary proteins is the enzymatic liberation during digestion of a mixture composed of peptides and 18-20 free amino-acids⁴. Because of the interactions between the amino-acids in competing for several relatively specific transfer mechanisms, the total rate of absorption of amino-acids from a mixture need not be closely related to the absorption rates of the same amino-acids when measured singly, but will depend on the composition of the mixture present in the intestinal lumen⁴. There is also evidence that during absorption for 1 h of glycine *in vitro*⁵ and of protein hydrolysate *in vivo*⁶ there is an incorporation of the absorbed amino-acids into the protein of rat intestinal mucosal cells. This communication records an investigation of amino-acid transport and protein synthesis in rat intestine during absorption of an amino-acid mixture *in vitro*.

Amino-acid transport was measured over 8 min as the entry of ¹⁴C-labelled amino-acids into the tissue water and proteins of rings of jejunum prepared from male albino rats ranging in weight from 260 to 300 g. The rings⁷ (2-5 mg dry weight) were incubated in 2.5 ml. of medium containing a mixture of 18 amino-acids giving a total amino-acid concentration of 1.7 mM, and containing 0.4 μC of a ¹⁴C-labelled protein hydrolysate ('CFB 25', Radiochemical Centre, Amersham). The incubations were terminated by the addition of an excess of an unlabelled casein hydrolysate and the rings rapidly removed from the medium, blotted, and transferred to 3 ml. 0.5 M perchloric acid at 0-5° C. The tissue was dispersed with a glass rod and the precipitated protein removed by centrifugation. An aliquot of the supernatant was counted to give a measure of the amount of labelled material in the perchloric acid extract. A correction was made for the carry-over of label from the medium by counting similar aliquots of perchloric acid extracts of rings incubated for 15 sec in a medium identical except for the presence of the excess of unlabelled casein hydrolysate. Apart from this correction no attempt was made to allow for the extracellular space or for any non-absorbing tissue present in the rings. If such corrections were made, the ratio of the concentration of amino-acids in the tissue fluid to that in the medium (T/M) would tend to increase when the ratio was greater than 1.

To measure the amount of amino-acid incorporation, the precipitated protein was washed in perchloric acid, dissolved in N sodium hydroxide, and then reprecipitated. This process was repeated several times according to the method of Truman and Korner⁸. Both the acid and the base used in this procedure contained an excess of unlabelled casein hydrolysate. The precipitated protein was then extracted with lipid solvents, dried with ether, dissolved in formic acid and finally transferred to a previously weighed planchet. After the sample was dried, the planchet was re-weighed and counted.

In Table 1 the figures for transport show the total amount of amino-acid entering the rings during incubation and, therefore, includes both amino-acids incorporated into protein, as well as 'free' amino-acids. The T/M values show the ratio of 'free' amino-acid (that is, the radioactivity in perchloric acid soluble form) in the tissue water to that in the medium at the end of the incubation. It is evident that mucosal tissue *in vitro* can accumulate amino-acids from a protein hydrolysate to give a value of T/M which is significantly greater than 1. However, the substitution of K⁺ for Na⁺ in the incubation medium reduced the rate of transport to a low level and prevented accumulation. It seems significant to us that the only condition in which we failed to observe an accumulation of amino-acids was when the cation gradient between the cells and medium was abolished. In other similar experiments in which Na⁺ was replaced by Li⁺ or choline, T/M values significantly greater than 1 were obtained. Table 1 also indicates that in the presence of glucose neither anoxic conditions, 2,4-dinitrophenol (5×10^{-4} M) nor oligomycin ($10 \mu\text{g ml}^{-1}$) prevented accumulation from taking place, and oligomycin actually increased the rate of transport. These findings suggest that the energy for amino-acid transport is provided by the movement of ions, and that these movements can be sustained by energy derived from glycolysis rather than from oxidative phosphorylation. Thus it has previously been found that in the presence of glucose, the mucosal tissue K⁺ is maintained under anaerobic conditions⁹.

Table 1. NET ACCUMULATION OF A MIXTURE OF AMINO-ACIDS IN RINGS OF RAT INTESTINE AFTER 8 MIN ABSORPTION. INCUBATION MEDIUM: HCO₃-RINGER, 500 MG/100 ML. GLUCOSE

Values are of means \pm S.E.M. (No. of observations)			
Predominant cation incubation medium	Additions	Net amino-acid transport 10^{-4} M/mg tissue dry weight	T/M
Na ⁺	None	20.4 \pm 1.4 (10)	2.57 \pm 0.25 (10)
K ⁺	None	8.1 \pm 1.3 (6)	0.86 \pm 0.14 (6)
Na ⁺	5×10^{-4} M DNP	22.2 \pm 2.9 (9)	2.50 \pm 0.30 (9)
Na ⁺	10 $\mu\text{g/ml}$ oligomycin	32.7 \pm 2.7 (9)	3.72 \pm 0.31 (9)
Na ⁺	'Anaerobic' (average pO_2 7.5 torr)	19.9 \pm 1.9 (6)	2.26 \pm 0.23 (6)

Table 2. NET INCORPORATION OF A MIXTURE OF AMINO-ACIDS INTO THE PROTEIN OF RINGS OF RAT INTESTINE AFTER 8 MIN INCUBATION

Values are of means \pm S.E.M. (No. of observations)			
Predominant cation incubation medium	Additions	Amino-acid incorporated into protein 10^{-4} M/mg. tissue dry weight	% incorporation
Na ⁺	None	2.31 \pm 0.34 (10)	11.2 \pm 1.3 (10)
K ⁺	None	0.64 \pm 0.028 (6)	9.0 \pm 1.5 (6)
Na ⁺	5×10^{-4} M DNP	0.26 \pm 0.04 (9)	1.4 \pm 0.27 (9)
Na ⁺	10 $\mu\text{g/ml}$ oligomycin	2.32 \pm 0.45 (9)	6.9 \pm 0.96 (9)
Na ⁺	'Anaerobic' (average pO_2 7.5 torr)	0.13 \pm 0.03 (6)	0.7 \pm 0.2 (6)

Table 2 shows, for the same experiments as those in Table 1, the amount of amino-acid incorporated in protein together with the percentage of the total amount of amino-acid entering the jejunal rings which is incorporated in the protein. It is seen that of the amino-acids taken up by the tissue, a remarkably high proportion was incorporated into protein during the 8 min incubation period. Although the substitution of K⁺ for Na⁺ reduced the absolute extent of the incorporation, it

did not change the percentage incorporation. The same rough correspondence between changes in transport rate and changes in the extent of incorporation has been noted over a range of different conditions. However, unlike transport, the incorporation of amino-acids into protein requires energy supplied by oxidative phosphorylation, since dinitrophenol and anoxia virtually abolished incorporation. Oligomycin, at a concentration sufficient to slow the rate of oxygen uptake significantly, did not inhibit the amino-acid incorporation.

We conclude that our findings are consistent with the view that the existence of a cation gradient between the mucosal fluid and the mucosal cells appears to be a necessary condition for the 'active' transport of amino-acids into these cells and that, in the presence of glucose, such a gradient can be maintained without the participation of energy from aerobic sources. The processes underlying the incorporation of amino-acids into the proteins of the absorbing cells, although dependent on the rate of transport of the amino-acids into the cells, have, in contrast, an absolute requirement for energy derived from oxidative reactions. The fact that the incorporation of amino-acid is independent of the presence of oligomycin indicates that, as is the case for both ion accumulation^{10,11} and amino-acid incorporation¹²⁻¹⁴ in mitochondria, ATP may not be an obligatory intermediary in supply of energy for these processes.

Changes in Amino-nitrogen Content of Solutions of γ -Keratose from Wool Keratin

NUMEROUS workers¹⁻³ have fractionated wool keratin after oxidation of disulphide bonds with performic or peracetic acids into three fractions, α , β and γ -keratose (β -keratose is insoluble in water, α -keratose is that fraction precipitating at pH 4 and γ -keratose the remaining fraction). While these fractions vary somewhat in the amounts of terminal amino-acids⁴, no comments have yet been made on any changes in constitution of the isolated fraction of γ -keratose on re-dissolution in water. As an introduction to some work on the hydrolysis of γ -keratose (prepared by the method of Corfield, Robson and Skinner²), the free amino-nitrogen value was determined by reaction with nitrous acid, the method of Van Slyke^{5,6}, and it was found that reproducible results were not obtained on samples until the solution had been standing for some time. Accordingly the determination of amino-nitrogen of γ -keratose (10 mg/ml.) at various periods of time after dissolution was carried out and plotted as a function of time in acid (0.2 M potassium hydrogen phthalate buffer, pH 4), alkaline (0.2 M boric acid in 0.2 M potassium chloride buffer, pH 10), salt (0.2 M potassium chloride) and simple aqueous solution. The results are shown in Fig. 1.

Fig. 1. Amino-nitrogen of γ -keratose. \bullet , in water; \circ , in 0.2 M potassium chloride; \bullet , in buffer, pH 10, \bullet , in buffer, pH 4

With the exception of γ -keratose under acid conditions, the amino-nitrogen value rose to a steady value over a period of time, the time depending on the pH of the solution. Although apparently instantaneous in acid solution, the equilibration time is longer in simple aqueous solution than in salt or alkaline solution.

This effect was definitely not bacteriological decomposition, as deliberate introduction of non-sterile air on particular runs showed increased amino-nitrogen figures after a lag of about two days.

Use of the biuret reaction⁷ indicated no peptide bond breakdown, as readings taken 20 min and 24 h after dissolution showed no statistical difference. $[\alpha]_D$ is very sensitive to the configuration of the peptide chain⁸, but on redissolution of γ -keratose no significant changes in $[\alpha]_D$ were observed.

The reason for this change therefore remains unexplained, but for further structural studies it would appear safer either to equilibrate the solution by standing or treating with acid at pH 4 before use.

Binding of Tetracyclines to Bone

TETRACYCLINE (I) (ref. 1) and its derivatives oxytetracycline, chlortetracycline and (1-pyrrolidinylmethyl)-tetracycline² are taken up in newly-formed bone after injection into the living organism, to form a zone that is intensely fluorescent under ultra-violet light. This reaction, which occurs wherever there is active deposition of new bone³, can be used for the detection of calcification. Because mineralized dead bone also takes up tetracycline on every surface (including, although to a lesser extent, the non-growing surfaces)⁴, the reaction does not depend on the activity of living bone cells or on the integrity of the physical properties of the intercellular components. Instead, there appears to be a direct reaction between tetracycline and one or more inorganic components of the mineralized tissue, the most likely species being

hydroxyapatite, $\text{Ca}_{10}(\text{PO}_4)_6(\text{OH})_2$, which is the major constituent of all such tissue⁵. A plausible suggestion as to the nature of the bonding involved is now offered.

Tetracyclines have well-defined metal-complexing abilities⁶, and spectra evidence indicates that the phenolic β -diketone group attached to carbons 10, 11, and 12 is concerned in complex formation with calcium and other metal ions⁷. However, if the attachment of tetracyclines to bone surfaces is through the calcium ions of the latter, the binding is much stronger than would be expected from the stability of the metal complexes in aqueous solution. For example, the stability constant of the 1:1 magnesium-tetracycline complex⁸ is only about 10^4 , and for electrostatic reasons the corresponding calcium complex should have a comparable, or even smaller, stability constant. Present observations suggest that this relative weakness is more than offset by a particularly favourable stereochemistry of the hydroxyapatite crystal.

Using the published^{9,10} crystal structure data, models of several unit cells of hydroxyapatite have been constructed to a scale of 0.8 in. \equiv 1 Å. For this purpose, pointed 1/8-in. diameter brass rods, carrying short pieces of plastic tubing to denote the positions of atoms, were inserted into the appropriate positions of a grid drawn on a polyurethane baseboard. This scale was chosen to be the same as for the Courtauld atomic models used in constructing a molecule of tetracycline of the correct¹⁰ stereochemistry.

When the tetracycline molecule was placed edge-on to the hydroxyapatite structure (that is, perpendicular to the a, b plane), there was a close superposition of three oxygen atoms of the former on to three calcium ions of the latter, provided the tetracycline replaced two phosphate ions. The relevant calcium and phosphate ions are indicated in Fig. 1. (For the complete structure of hydroxyapatite, see ref. 8.) These calcium ions fit, within about 0.1 Å, the oxygen atoms (at least one of which is present as an anion) on C_{10} and C_{12} , and the oxygen of the carbamoyl group on C_2 while, at the same time, the structure remains sufficiently open to enable the insertion of any hydroxyl ions that may be needed to maintain electrical neutrality. I suggest that it is the ability to form bonds through all three positions concurrently and without steric strain that is responsible for the observed strong adhesion of tetracyclines to bone surfaces.

In the resulting complex the tetracycline molecule presents an essentially hydrophobic surface to its environment, so that there would be little tendency for the complex to dissociate in aqueous media. Also, the portion of the tetracycline molecule that is substituted in forming 5-hydroxy- (terramycin), 7-chloro- (aureomycin), 7-bromo-, and similar derivatives is remote from the binding

Fig. 1. Projection of two unit cells of hydroxyapatite on the a, b plane, to show the locations of the calcium ions on which tetracycline can be fitted. Dimensions are (ref. 3) $a = b = 9.432$ Å, c (perpendicular to a and b) = 6.881 Å. The broken lines enclose the phosphate groups that are displaced by the tetracycline. Numbers indicate heights in terms of c .

sites and hence exerts no direct steric effects. Fluorapatite is isomorphous with hydroxyapatite, and crystal dimensions¹¹ are similar, so that the same type of tetracycline binding probably also occurs in fluorapatite.

PHYSIOLOGY

Determination of Nicotine in Smokers' Urine by Gas Chromatography

THE highly controversial subject of the effects of smoking on health has been extensively investigated and reviewed in recent years^{1,2}. It has been reported that nicotine has an effect on the cardiovascular system. However, its relation to coronary disease is not fully understood. The absorption of nicotine as the result of smoking is dependent on a number of factors³. The quantitation of nicotine and its metabolites in the body fluids of smokers would be helpful for the investigation of the relation between nicotine exposure and heart disease. It should also give a more reliable estimate of the quantities of other tobacco smoke ingredients to which the body is exposed. This communication describes such a method.

Corcoran has demonstrated⁴ that nicotine is present in smokers' urine. McKennis *et al.*⁵ have found by isolation from urine that cotinine is the main metabolite of nicotine in human.

Gas chromatography has been used by Quin⁶ to detect nicotine and related compounds in tobacco and in cigarette smoke. The presence of at least sixteen basic compounds was demonstrated. This technique has been used to quantitate nicotine in tobacco⁷.

The procedure used in the work recorded here is as follows: 5-ml. portions of 24-h urine collections (smokers or non-smokers) were adjusted to pH 1 with 6 M sulphuric acid and exhaustively extracted with methylene chloride. This removed neutral, phenolic and other acidic materials. The aqueous layer was adjusted to pH 11 with 50 per cent aqueous sodium hydroxide. The liberated nitrogen bases were then extracted immediately with methylene chloride and the aqueous layer discarded. The extract was then acidified with hydrochloric acid and evaporated to dryness with nitrogen. The residue was made alkaline with 3 μ l. of 2 N aqueous sodium hydroxide to liberate the nitrogen bases and diluted with 200 μ l. of acetonitrile. Aliquots of this solution (2–3 μ l.) were injected into the gas chromatograph. To determine recoveries during the extraction procedure, nicotine randomly tritiated (specific activity 40 mc./mmole) was added to the urine. Recoveries ranged from 60 to 95 per cent.

A Glowall Corp. 'Chromalab' gas chromatograph equipped with a strontium-90/argon ionization detector was used. The column was a glass coil 12 ft. long and 3.4 mm internal diameter arranged for on column liquid injection. It was packed with 14.5 per cent SE-30

silicone gum rubber on 'Anakrom ABS', 100–110 mesh. The column was kept at 200° and argon flow rates of 10–20 c.c./min were used. The detector was operated at 1,350 V. An internal standard (3-methyl, 3-phenyl piperidine) was added to the acetonitrile solution as a retention time reference. It also served for the purpose of quantitation using the peak height ratio method. (–) Nicotine was obtained commercially. (–) Cotinine was obtained from Dr. H. McKennis. (We thank him for this, and Unimed, Inc., for gifts of other metabolites.) Both substances showed single peaks on gas chromatography.

Fig. 1 shows the separation of (–) nicotine, (–) cotinine and the internal standard. A calibration curve

Fig. 1. Gas liquid chromatography of authentic (–) nicotine (A); 3-methyl 3-phenyl piperidine (B); and (–) cotinine (C)

Fig. 2. Calibration curve for gas liquid chromatography of nicotine

Fig. 3. Gas chromatography of extract from smoker's and non-smoker's urine. A, Nicotine; B, added standard 3-methyl 3-phenyl piperidine; C, cotinine

relating peak height ratio to weight ratio of nicotine to standard is shown in Fig. 2. The extract of a cigarette smoker's urine gave the curve shown in Fig. 3. The nicotine and cotinine peaks were identified by their retention times and by their augmentation on addition of authentic nicotine and cotinine. This curve shows that the method is selective for nicotine and cotinine since no other compounds in the urine interfere. Comparison with a non-smoker's urine confirms this (Fig. 3). The overall reproducibility of the method for nicotine was found to be ± 14 per cent $n = 4$, $P = 0.99$. Analysis of non-smokers' urine to which had been added known quantities of nicotine in the range 5–10 mg/l. showed overall recoveries of 80 and 92 per cent. Some preliminary results are shown in Table 1.

Table 1. NICOTINE IN SMOKERS' URINE

Subject	Tobacco	No. or amount	Nicotine excretion mg/day
1	Cigarettes	4	<0.1
2	"	10	0.27
3	"	25	0.74
4	"	27	1.37
3	"	30	10.5
3	"	31	5.46
5	"	31	9.06
6	"	43	5.81
7	Cigars	20 g	<0.1
8	"	55 g	8.50
9	Pipe	20 g	0.11

The variation in nicotine excretion between individuals, tobacco forms and amount of tobacco consumed is probably a reflexion of the smoking habits of the individual. Other factors which have been discussed in ref. 3 are probably important.

This work was supported by a grant from the U.S. Council for Tobacco Research.

Diurnal Variations in Ovarian Ascorbic Acid Content of Pseudopregnant Immature Rats used in Parlow's Test

DEPLETION of ascorbic acid from the ovary of the immature rat rendered pseudopregnant by treatment with pregnant mare's serum (PMS) and human chorionic gonadotrophin (HCG) is used as an assay for luteinizing hormone (LH). A significant diurnal variation in the ovarian ascorbic acid (OAA) content was observed by Stevens¹ in such rats. These variations may be important in the assay of LH by Parlow's method.

We considered it to be of interest to study the variations in the OAA content of our rats by comparing the values obtained in the morning (8–12 a.m.) with those obtained in the afternoon (4–8 p.m.) during a period February 1963–August 1964.

The values that we determined correspond to the concentration of ascorbic acid in the left ovary which acts as a control with respect to the right one in experiments

intended to study the LH-releasing substance of human brain². The concentrations are expressed in mg/100 g gland. Immature albino rats of our own breeding were injected at the age of 26 days with 50 i.u. of PMS (Gormon-Laboratorio Richter, Chile) and, 48–60 h later, with 25 i.u. of HCG (API-Ayeris Laboratories Inc.). Five to eight days later the animals were investigated, but until then the rats were housed in a special room illuminated for 14 h each day (7 a.m. until 9 p.m.) and allowed permanent access to food in the form of pellets of constant composition. The ascorbic acid content of the left ovary was measured by means of the method of Roe and Kuether³. The rats were anaesthetized by an intraperitoneal injection of 'Avertin' (Winthrop Laboratories), and the ovaries carefully dissected out and weighed on a Roller Smith torsion balance to the nearest 0.1 mg. The experiments were performed from 8 to 12 a.m. and from 4 to 8 p.m.

A total of 571 rats were used during 1963, 384 in the morning and 187 in the afternoon. During 1964, 542 rats were used, 355 in the morning and 187 in the afternoon.

The means of the morning and afternoon values (Table 1) were compared, assuming that the standard deviations were not necessarily equal⁴.

Table 1. OVARIAN ASCORBIC ACID CONCENTRATION IN THE MORNING AND IN THE AFTERNOON DURING 1963 AND 1964

	8–12 a.m.	4–8 p.m.
1963	85.34 \pm 18.23 (384)	77.28 \pm 19.67 (187)
1964	112.39 \pm 23.46 (355)	110.87 \pm 24.12 (187)

Values are expressed in mg/100 g \pm S.E. The number of test animals is shown in brackets.

The t' test of significance is given by:

$$t' = \frac{\bar{x} - \bar{y}}{\sqrt{s_x^2/n_x + s_y^2/n_y}}$$

$$v = \frac{(s_x^2/n_x + s_y^2/n_y)^2}{(s_x^2/n_x)^2 + (s_y^2/n_y)^2} - 2$$

$$(n_x + 1) + (n_y + 1)$$

All the data were processed in an IBM 1620 computer, at the Centro de Computación Universidad Católica, Santiago.

In Figs. 1 and 2 and in Table 1 it can be seen that the OAA showed higher values during 1964 than during 1963. During the low level period, morning values were significantly higher than the afternoon values ($P < 0.005$). During the 1964 period, with values permanently higher than 90 mg/100 g, the difference was not significant. The results obtained during 1963 are in keeping with those reported by V. C. Stevens¹, who found most ascorbic acid values coincident with our range of that period. These results suggest that rats with high levels of OAA may be more convenient for use in Parlow's test because they do not show such great diurnal variations as do those with low levels.

Ovarian ascorbic acid level and its sensitivity to LH depends on the luteotrophin secretion as shown by the

Fig. 1. Ovarian ascorbic acid concentration S.D. from February to December 1963. The number of set animals used is shown at the base of each bar. White, 8–12 a.m.; hatched, 4–8 p.m.

Fig. 2. Ovarian ascorbic acid concentration from February to August 1964. White, 8-12 a.m., hatched, 4-8 p.m.

rapid loss of ascorbic acid after hypophysectomy⁵⁻⁷ and the prevention of such effect by luteotrophin injection or pituitary autografts in the kidney⁸ which produce only luteotrophin.

Rats made pseudopregnant by treatment with exogenous gonadotrophins (as used for Parlow's test) show signs of luteal function, which is promoted by pituitary luteotrophin secretion during a period of 10-12 days. We may suppose that variations in luteotrophin secretion may influence the OAA concentration. Recently, R. H. Clark and B. L. Baker⁹ have shown a circadian periodicity in the concentration of luteotrophin in the rat hypophysis with highest values at 4 p.m. and no significant changes at other times of day. These changes in hormone content are most probably the consequence of changes in secretion rate, which is lowest at the time coincident with the highest pituitary concentration. This assumption enables us to explain the lower levels of ascorbic acid in afternoon determinations, because during this period of the day the delivery of luteotrophin is low.

We can offer no explanation for the difference in OAA observed between 1963 and 1964; the method of handling the animals was the same throughout the whole period.

We thank E. Bollo, Centro de Computación Universidad Católica, Santiago, for undertaking the statistical analysis of the results, and Miss Gladys Suarez for her help.

Intracellular Chloride Activity of Crayfish Giant Axons

RECENT measurements of chloride concentrations in the squid giant nerve axon have indicated that intracellular chloride ion is of higher concentration than would be expected if chloride ions were distributed across the cell

Fig. 1

membrane in equilibrium with the transmembrane potential¹. Measurements of intracellular chloride activity of squid giant axons with an Ag-AgCl electrode have also indicated higher intracellular chloride activities than could be accounted for from equilibrium considerations². Similarly, it has also been found in smooth muscle that intracellular chloride is of higher concentration than expected^{3,4}. In this communication, experiments are described which indicate that the intracellular chloride activity of crayfish giant axons (*Procambarus clarkii*) is higher than that expected from considerations based on chloride being distributed in equilibrium with the membrane potential. These experimental results are based on chloride activity measurements made with an intracellular Ag-AgCl electrode.

The experiments consisted of dissecting free from crayfish the ventral nerve chord, which contains several giant axons, and mounting the isolated nerve chord in a chamber (Fig. 1) containing van Harreveld's saline of the following composition: NaCl, 205 mM; KCl, 5.4 mM; CaCl₂, 13.5 mM; MgCl₂, 2.6 mM; NaHCO₃, 2.3 mM; pH adjusted to 7.4 by adding small amounts of HCl.

In the chamber holding the nerve was also placed a long KCl-filled micro-pipette cemented with insulating lacquer to an Ag-AgCl electrode. These electrodes were inserted length-wise into a giant axon from one end of the nerve. Connecting the physiological saline to earth was a reference KCl-AgCl electrode. The micro-pipette served to record transmembrane potential when inserted into the nerve axon and also acted as a reference electrode for the Ag-AgCl electrode for measuring chloride activity. The Ag-AgCl electrodes were made by pulling out 1-2 mm-diam. glass tubing inside of which was coiled 25 micron diameter wire of either silver or platinum. Long glass-covered lengths of wire were obtained with diameters initially about 50μ which increased to 100μ after 5-10 mm. Silver was plated on to the exposed wire end from an AgNO₃ and KCN plating solution. Silver chloride was deposited on the silver plate by chloriding in a 0.1 N HCl solution until 15-25 per cent of the silver plate was chlorodized. In some instances, the electrodes made with silver wire were chlorided directly without the additional silver plating being deposited. In general, the electrodes with silver plate on platinum wire were more stable. Erratic behaviour and incorrect potential changes with chloride shifts occurred occasionally with the electrodes, most often with the electrodes utilizing silver wire. This erratic behaviour was found to result in part from poor sealing of the wire to the glass insulation which exposed unchlorided metal to the solutions. For this reason, the electrodes were always calibrated before use.

Both the external bath reference electrode and cannulating micro-pipette electrode were filled with 3 M KCl to minimize liquid junction potentials and connected to Ag-AgCl electrodes. Potentials were recorded with an electrometer amplifier. The micro-pipette electrodes had tip diameters of less than 1μ to minimize the effect which chloride diffusion from the pipette tip would have on intracellular activities. The magnitude and importance of this chloride diffusion were investigated by measuring the

chloride activity gradient near the tip of a 3 M KCl-filled micro-pipette placed inside a giant axon. To accomplish this, a 3 M KCl-filled micro-pipette was inserted into one end of the axon, and from the opposite end of the axon the Ag-AgCl electrode was inserted and advanced toward the micro-pipette, which was held stationary. No change in measured chloride activity was detected until the Ag-AgCl electrode touched the micro-pipette tip, and even then the potential change in the chloride electrode was less than one millivolt. The intracellular chloride was therefore considered unaffected by chloride diffusion from the tip of the micro-pipette electrode.

Before the electrodes were inserted into one of the giant axons to measure membrane potential and chloride activity, calibration of the Ag-AgCl electrode was performed to determine if the electrodes functioned satisfactorily for measuring chloride activity. Calibration of the Ag-AgCl electrode was accomplished by changing the chloride activity of the van Harreveld's solution and recording the potential change of the Ag-AgCl electrode with respect to the micro-pipette electrode. Chloride was changed in the van Harreveld's solution by a one-to-one substitution with propionate or glucuronate ions in order to maintain constant ionic strength and activity coefficients. The possibility that activity coefficients might change when chloride was replaced with a weaker univalent ion was investigated by comparing the sodium activity of the different solutions with a sodium-sensitive glass electrode. These measurements showed no change in sodium activity for the different chloride solutions in which sodium and total ion concentrations were kept constant. In addition, the chloride electrodes gave the thermodynamically expected potential changes with chloride shifts, which indicated no change in activity coefficients. This indicated that activity coefficients remained constant in the different calibrating solutions. In the calibration the chloride activity changes were therefore directly proportional to the chloride concentration changes. In the external van Harreveld's solution, the activity coefficient for both the sodium and chloride ion was taken as 0.72. These activity coefficients were calculated from potential measurements obtained, with a sodium glass electrode and an Ag-AgCl electrode measured against a saturated KCl calomel cell reference, first in 0.001 M NaCl and then in van Harreveld's solution. The activity coefficients of sodium and chloride in 0.001 M NaCl were assumed equal and taken as 0.966 (ref. 5) from which the activity coefficients in van Harreveld's solution were calculated.

After determining the adequacy of the Ag-AgCl electrode for measuring chloride activities, an opening was made at one end of one of the giant axons lying in the ventral nerve chord. Into this opening was inserted the micro-pipette and Ag-AgCl electrode for distances of 5–10 mm. The measured potential of the micro-pipette with respect to the external bath electrode gave the membrane potential while the potential of the Ag-AgCl electrode with respect to the intracellular micro-pipette as a reference gave the intracellular chloride activity.

These simultaneous measurements of intracellular chloride activity and membrane potential were performed successfully on 29 different giant axons of crayfish (*Procambarus clarkii*) over a period of one year. The axon diameters varied from 100 to 150 μ , with dissected lengths of more than 3 cm. The results at average room temperature of 20° C gave a transmembrane potential of 80.3 ± 0.8 mV (mean \pm S.E.). The change in the potential of the chloride electrode corresponded to an intracellular chloride activity of 25.2 ± 2.9 mM/l. (mean \pm S.E.). If the activity coefficient of intracellular chloride is taken to be approximately that of the external physiological saline^{1,6,7}, the corresponding intracellular chloride concentration is 35 ± 4 mM/l. (mean \pm S.E.). If intracellular chloride ions are distributed in equilibrium with the transmembrane potential, the expected intracellular chloride activity should have been 7.3 mM/l. These results, which give an

intracellular chloride activity three and a half times higher than expected from equilibrium considerations, may be explained on the basis of chloride ion being actively transported in addition to sodium and possibly potassium ions. These experiments suggest, therefore, that in the crayfish nerve, and as has been suggested for the squid axon¹, none of the dominant ions is passively distributed in equilibrium in accordance with its electrochemical potentials, but instead active transport is probably more general and involves all these ions.

PHARMACOLOGY

Effects of Propylthiouracil and Thyroid Feeding on the Response of Mice to Injected Convulsant Barbiturate

In 1961, Carrier and Buday¹ enumerated the substances the toxicity of which is increased in hyperthyroid animals. Among these was hexobarbital². Prange *et al.*³ showed that mice fed desiccated thyroid slept longer than controls after injection of pentobarbital, while mice fed propylthiouracil (PTU) slept less.

Ellinwood and Prange⁴ explored these relationships in connexion with epinephrine pretreatment. Both epinephrine and thyroid feeding increased sleeping time to pentobarbital, but there was no additive effect when both pretreatments were used. PTU-fed mice slept a shorter time than controls. Like controls, however, their sleeping time could be increased by epinephrine pretreatment. The duration of these effects after the cessation of the various pretreatments was delineated.

A thyroid-induced enhancement of mortality and a PTU diminution has been described also for the anti-depressant drug imipramine^{5,6}. Prange *et al.*⁷ suggest that in the case of pentobarbital, at least, the effect of PTU is not due to hypothyroidism *per se* since thyroidectomized rats sleep longer, and maintain tissue levels of pentobarbital longer, than controls. Probably PTU induces activity of liver enzymes that degrade certain substances including pentobarbital.

In light of the foregoing, it was considered of interest to study the effects of altered thyroid function on a drug that is a structural barbiturate but a pharmacologic stimulant, 5-(1,3-dimethylbutyl)-5-ethyl barbituric acid (DMBEB).

Young male Swiss-Webster white mice were given 0.2 per cent PTU in their water for 30 days, or fed 2 per cent desiccated thyroid in their food for 4 days, or given tap water and standard lab chow. DMBEB was prepared in isotonic saline, 1 mg per ml. Animals were injected intraperitoneally with various doses; 30 PTU-fed mice; 40 control mice; 30 thyroid-fed mice. All animals showed signs of gross stimulation, and those that died did so within half an hour. Terminal convulsions were usually observed. The dose-mortality data were analysed according to the method of Litchfield and Wilcoxon⁸. The following LD_{50} s were estimated with upper and lower

Fig. 1. Half-hour mortality of adult male Swiss Webster white mice after intraperitoneal injection of 5-(1,3-dimethylbutyl)-5-ethyl barbituric acid

confidence limits: PTU-fed, 27.0 mg/kg (31.1–23.5); controls, 21.0 mg/kg (24.8–18.0); thyroid-fed, 12.2 mg/kg (13.9–11.1). These data are shown in Fig. 1. It was found that the LD_{50} for PTU-fed mice was statistically significantly greater than for controls ($P < 0.05$); the LD_{50} for thyroid-fed mice was significantly less than for controls ($P < 0.05$).

We considered it desirable to study another parameter of drug effect. Sleep time, of course, could not be measured, as in previous experiments; we elected to measure activity. A device for this purpose was obtained from Woodard Research Corporation, Herndon, Virginia. It consists of a doughnut-shaped cage (outer diameter 14½ in.) with a wire mesh floor. A centre core emits six infra-red beams directed toward photocells in the perimeter. When a light beam is broken, the impulse is recorded on a counter where such events are shown cumulatively. An animal must purposefully move about, as in exploring behaviour, to acquire a high score.

Animals with the various pre-treatments were injected intraperitoneally every ten seconds with saline in groups of 5 (cage mates) and placed in the cage, which was covered to exclude light. After brief initial excitement, all groups showed decreasing activity reaching a stable low level after about one hour. Thyroid-fed mice showed a pattern identical to the other two groups but at a lower level of activity throughout the time span. Observation of the mice revealed that thyroid-fed mice cringed, appeared frightened and tended to huddle when left alone. Only when externally stimulated did they dart about. After saline injection, PTU-fed and control mice showed similar patterns of spontaneous activity.

Other mice from the various pretreatment groups were injected intraperitoneally with DMBEB, 5 mg/kg, and placed in the cage. All groups now showed decreased spontaneous activity as compared with respective controls. That is, they resembled and behaved like (saline-injected) thyroid-fed mice. This experiment was carried out twice, with different mice. Data were plotted for activity per minute against time. Inspection of the data showed that the DMBEB inhibition of spontaneous activity was most pronounced in thyroid-fed mice and least pronounced in PTU-fed mice. In another experiment, activity after DMBEB injection was recorded every 10 sec for 10 min and no difference in onset of drug action between groups could be shown. Here, as in other work⁷, we suggest that possible differences in absorption between groups can scarcely be a sufficient explanation of the phenomena reported.

On the basis of the foregoing findings we concluded that in mice thyroid feeding potentiates the action of DMBEB while PTU feeding diminishes it. The problem of differen-

tiating thyroid-fed mice from others on the basis of activity deserves brief comment. In such mice, spontaneous activity as measured by our technique was decreased. This finding allowed differentiation but in a direction that seems paradoxical. Again, a stimulating drug, paradoxically, reduced spontaneous activity in all groups, but had its greatest effect in thyroid-fed mice. The use of evoked activity and the measurements of fine movements might yield group differentiation in the expected directions.

Epileptogenic Effect of Extradural and Extracranial Cobalt

CHRONIC epileptogenic foci have been produced in rats and mice by metallic cobalt powder placed in the brain or on its surface^{1,2}. The lesions were destructive; necrosis and abscess formation were common. We have studied the epileptogenic effects of extradural and extracranial cobalt.

Fifty female Holtzman rats with initial body-weight of 250–300 g were divided into five groups of ten each. Trepanation of right frontal bone, 1–3 mm wide, was performed in four groups. One of these groups received no further treatment. Cobalt powder of 325 mesh was applied topically to the intact dura (extradural), or to the surface of the brain (subdural), or a pellet of the powder in the lumen of a 20-gauge needle was implanted into the brain (intracerebral). In the fifth group, the skull bone was drilled only part way through, and cobalt powder was applied over the remaining layer of intact bone (extracranial).

Twenty days later, the epileptogenic effect of cobalt was determined with injectable 'Indoklon'³ (a 10 per cent solution of the volatile convulsant, hexafluorodithyl ether, in polyethylene glycol 55 per cent, U.S.P., alcohol 20 per cent, and water 15 per cent). A single intraperitoneal dose of 0.1 ml./100 g body-weight caused convulsions in most of the cobalt-treated rats but not in the normal controls (Table 1). After a ten-day rest, 'Metrazol' (penta-methylentrazol) thresholds were determined. 'Metrazol', 15 mg/kg, was injected repeatedly, intraperitoneally, at 15-min intervals until convulsions occurred. The average number of injections was less in cobalt-treated rats than in normal controls (Table 1), that is, the 'Metrazol' threshold was reduced. Extradural cobalt was as effective

Table 1. RESPONSE OF EXPERIMENTAL EPILEPTIC RATS TO 'INDOKLON' AND 'METRAZOL'

Location of cobalt	'Indoklon'* convulsion incidence (%)	'Metrazol'† threshold	Brain necrosis and abscesses (%)
Sham operation	0	3	0
Extracranial	40	2.2	50
Extradural	70	1.8	40
Subdural	70	1.8	90
Intracerebral	70	2	100

* 0.10 ml. per 100 g body-weight.

† Average number of 'Metrazol' injections required to produce convulsion.

Fig. 1. Extradural cobalt application caused focal granulation tissue

Fig. 2. Intracerebral cobalt application caused extensive necrosis

as subdural or intracerebral cobalt in producing experimental epilepsy. Even extracranial cobalt was epileptogenic, although less effective than the other routes. Extradural and intracerebral cobalt (Fig. 1) caused less necrosis and fewer abscesses than subdural or intracerebral cobalt (Fig. 2). About half the brains from the former groups exhibited nothing more than meningeal adhesions, focal depression of the cortical surface, minimal subjacent necrosis and granulation tissue. Therefore, cobalt epilepsy can be produced without concomitant severe necrosis.

Formation of Amines in the Gastric Mucosa of the Rat

HISTAMINE may have some role, as yet unknown, in the chemical regulation of gastric secretion¹. This view is based on the effectiveness of histamine in producing acid secretion, on the presence of histamine in the gastric juice, and on the high concentration of histamine in the gastric mucosa of several species. The rich supply of histamine in this tissue in the rat is coincident with a high histidine decarboxylase activity², probably indicating a local synthesis of the amine. Several animal tissues contain L-3,4-dihydroxyphenylalanine (DOPA) decarboxylase, which attacks all aromatic amino-acids, including 5-hydroxytryptophan (5-HTP) and histidine³⁻⁵. This enzyme, however, decarboxylates histidine only inefficiently and the physiological significance of this aspect of

its function remains uncertain^{3,6}. Another more specific histidine decarboxylase has been demonstrated in the foetal rat^{7,8} and in the bone marrow of the adult rat⁹. In a recent investigation DOPA decarboxylase, as well as the specific histidine decarboxylase (cf. Weissbach *et al.*³), were demonstrated in the gastric mucosa of the rat¹⁰. While the presence of specific histidine decarboxylase seems to account for the formation of gastric histamine and ultimately for the postulated control of gastric secretion, the physiological significance of a high gastric DOPA decarboxylase activity is unknown.

The present study is a preliminary attempt to elucidate the possible significance of gastric DOPA decarboxylase. Saline suspensions of DL-DOPA or DL-5-HTP were injected intraperitoneally into rats in doses of 300 mg/kg body-weight and the concentration of amines in the entire stomach wall was determined at different times after injection (Fig. 1). The stomach was taken out, cut open along curvature minor, washed several times in saline and dried on filter paper to remove excess fluid. After weighing, the tissue was homogenized in acid according to routine techniques^{11,12}. Dopamine was extracted and isolated by ion exchange chromatography as described by Bertler *et al.*¹¹ and determined fluorometrically according to Carlsson and Waldeck¹². 5-Hydroxytryptamine was extracted and determined as described by Bogdanski *et al.*¹³.

While the stomach walls of untreated animals contained no dopamine and only moderate amounts of 5-hydroxytryptamine (cf. Ersparner¹⁴), large amounts of both amines could be demonstrated 1 or 2 h after injection of the precursors. The major part of the amines was found in the mucosa; the muscular layer contained very little. The concentration of amines in the pyloric part was found to be more than twice as high as in the fundus, a distribution which is similar to the distribution of DOPA decarboxylase¹⁰. In some animals, haemorrhagic erosions developed in the glandular portion of the gastric mucosa 2 or 3 h after administration of 5-HTP. This finding is in agreement with earlier observations by Haverback and Bogdanski¹⁵. Treatment with α -methyl DOPA or α -methyl-m-tyrosine (500 mg/kg i.p.) was found to produce marked inhibition of gastric DOPA decarboxylase as evidenced by direct estimation of the enzyme activity according to the radiometric method of Håkanson⁶. Injection of DL-5-HTP 2 h after administration of an enzyme inhibitor

Fig. 1. Concentration of dopamine and 5-hydroxytryptamine in the entire stomach wall of the rat at different time intervals after intraperitoneal injections of the respective precursor. Each point represents the mean value from at least four experiments. The vertical lines indicate standard error of the mean. The curves are approximated from the points. Open circles, 5-hydroxytryptamine; solid circles, dopamine

produced only a slight increase in gastric 5-hydroxytryptamine.

Preliminary evidence indicates that DOPA decarboxylase is located in a specific, enterochromaffin-like cell system in the gastric mucosa¹⁰. From the data available there seems to be little doubt that the gastric DOPA decarboxylase is physiologically active. The argument that the rather low concentration of dopamine and 5-hydroxytryptamine in the stomachs of untreated animals indicates inefficiency of the enzyme is not necessarily valid since a rapid turn-over would make accumulation of the amines impossible under normal conditions. It should be noted that while the gastric mucosa of several species seems to lack the specific histidine decarboxylase, high DOPA decarboxylase activity has been demonstrated in all species studied¹⁰, possibly indicating a general role for this enzyme in gastric function.

HAEMATOLOGY

A Factor stimulating DNA Synthesis derived from the Medium of Leucocyte Cultures

BAIN *et al.*^{1,2} have shown that when human peripheral blood leucocytes from two individuals are mixed and cultured, large immature cells appear and the incorporation of tritiated thymidine into DNA is stimulated. It has been suggested that variations in this response may reflect differences in the number of histocompatibility antigens shared by the donors of the cells¹⁻³. It has also been shown that transplantation antigens can be detected in the medium from tissue cultures of rabbit⁴ and dog⁵ spleen cells. We, therefore, decided to determine whether factors released into the medium from cultured peripheral blood leucocytes might stimulate tritiated thymidine uptake (radioactive content) in cultures of leucocytes from another individual.

The subjects were normal volunteers, unrelated to one another. The culture technique was as previously described^{1,2}. The cell cultures were prepared with sterile precautions. The leucocytes were suspended in TC-199 medium (Microbiological Associates, Inc., Bethesda, Maryland, U.S.A.) containing 20 per cent autologous plasma and penicillin (100 units/ml). In every instance the leucocyte count was approximately 2,000/mm³. For each culture, 4 ml. of cell suspension was placed in a 17 mm × 100 mm disposable plastic culture tube and incubated at 37° C.

After incubation for 24, 72 or 120 h at 37° C, the culture medium was collected from approximately 20

tubes containing mixed or unmixed cultures (total volume 60–80 ml.), and centrifuged at 1,500g for 15 min to remove cells and gross cellular debris. Leucocyte counts and smears were done on this supernatant; intact leucocytes were not found in any of these preparations. A portion of the medium was then spun in a Spinco model L preparative ultracentrifuge at 100,000g for 1 h. All but about 0.2 ml. of supernatant was removed from each centrifuge tube. The precipitate was resuspended by vigorous shaking and stirring with a Pasteur pipette, and the resuspended sediments were pooled (total volume about 2 ml.). The volume of the precipitate added to each culture tube represented that derived from 30 to 40 ml. of culture medium. There were then three culture medium preparations: (a) cell-free medium (*M*); (b) supernatant after centrifugation for 1 h at 100,000g (*S*); (c) precipitate after centrifugation for 1 h at 100,000g (*P*). Various volumes of the whole medium from the previous cultures, or fractions of this medium prepared as already described here, were added to freshly prepared leucocyte cultures from one of the original donors. At the same time, cultures of mixtures of intact cells from the same donors were again set up. All these cultures were incubated for five days at 37° C. Each culture was prepared in triplicate.

At the end of the incubation period, smears were made from one of the culture tubes and tritiated thymidine (specific activity 7.2 c./mmole) was added to give a concentration of 1 µc./ml. After 1 h at 37° C, radioactive content of cells was measured in the other two tubes as described previously².

When cell-free medium, or its fractions, from previously cultured leucocytes was added to fresh unmixed homologous leucocytes, it was found to induce the appearance of large basophilic cells and to increase the uptake of tritiated thymidine. The stimulating activity appeared to be concentrated in the precipitate obtained on ultracentrifugation of the culture medium from both mixed (Table 1) and unmixed leucocytes (Table 2). The activity of the precipitate was significantly higher than that noted in the cell-free medium before ultracentrifugation or in the supernatant after ultracentrifugation.

The activities of 1.0 ml. of the cell-free culture medium, *M*, and the supernatant after culture centrifugation, *S*, were approximately equal (Table 1). However, when the activities of 4.0 ml. of these materials from 5-day-old mixed cultures were tested, *M* was consistently more active than *S*. These findings indicate that only a fraction of the original activity can be found in the precipitate, *P*. The relatively high degree of activities of *P* was due to the fact that each ml. of *P* was derived from 30 to 40 ml. of *M*. The uptake of tritiated thymidine by leucocyte cultures from single donors to which fraction *P* had been

added was in no instance as great as that found in cultures of mixtures of intact leucocytes (Tables 1 and 2). The precipitate from mixed leucocyte cultures was more active than that from homologous unmixed leucocyte cultures. The precipitate from cultures of leucocytes from a single donor produced no blastogenesis when added to freshly prepared cultures from the same individual. The precipitate from 5-day cultures was more active than that from 3-day cultures, and the precipitate from a 24-h culture medium showed slight but still significant activity (Table 3). The stimulatory activity was increased by increasing the volume of the added medium. When the volume was doubled (2 ml.), a definite increase of stimulatory activity was observed in some, but not all, instances. When the volume was quadrupled (4 ml.), the activity almost uniformly was sharply increased.

These experiments have shown that when human blood leucocytes are cultured, a material is released into the culture medium which is concentrated by ultracentrifugation and which stimulates blastogenesis when added to cultures of homologous leucocytes. The amount of this material released into the culture medium seemed to be related to the numbers of large basophilic cells which appeared in the cultures. The results presented here permit no conclusions as to whether the presence of this factor precedes and stimulates the production of these blast cells or is produced by these cells. It is not known whether the stimulatory factor is secreted by these or other cells or is a sub-cellular fraction released into the medium as a result of damage or death of cells. At present, the nature of this factor is unknown. The absence of blastogenic effect when this material is added to cultures of autologous leucocytes demonstrates its antigenic specificity. It is possible that this factor may contain transplantation antigen⁴ or complexes between RNA and antigens.

In summary: (1) The medium from human leucocytes cultivated *in vitro* stimulated blastogenesis when added to cultures of homologous leucocytes. (2) Medium from mixed leucocyte cultures was more active than that from homologous unmixed leucocyte cultures, but was less active than mixtures of intact leucocytes from the same donors. (3) Medium from unmixed leucocyte cultures was inactive when added to cultures of autologous leucocytes. (4) Some activity was found in the precipitate obtained after ultracentrifugation.

A Lymphocyte-stimulating Factor produced *in vitro*

Bain, Vas and Lowenstein¹ have recently reported that when peripheral leucocytes of two individuals are cultured together, some of the cells enlarge and undergo mitosis. Bach and Hirschhorn² have further shown that not only intact cells, but also extracts of leucocytes, disrupted by freezing and thawing, could stimulate cells to divide. Experiments reported in this communication demonstrate that cell-free media obtained from leucocytes in culture contain mitogenic factor(s), and suggest that these factors might be produced by the cells *in vitro*.

Cells of normal human volunteers were cultured according to the method of Bain *et al.*¹ with the exception that no antibiotics were used. Single cultures contained 4×10^6 cells derived from one donor in a total volume of 4 ml. TC199 containing 10–20 per cent autologous plasma. Mixed cultures contained a total of 4×10^6 cells derived from two donors in the same volume of medium.

To test preparations for blastogenic activity the following procedure was used: Single or mixed cultures from cells of two donors were prepared; leucocytes in single, or in most experiments, in mixed cultures were treated after different periods of incubation by either one of the following procedures: centrifugation, three cycles of freezing and thawing, disruption by ultrasonic vibration, lysis in distilled water or heating at 50° C for 5 min. Cells, cell fragments, or cell-free culture media derived from these cultures were transferred for testing to single cultures initiated at the beginning of the experiment. The cultures were examined for blastogenesis 5 days after transfer.

Cell-free culture media used for assays were collected 1–5 days after initiation of the cultures. The tubes containing the cultures were centrifuged at 540g for 10 min. The medium was removed using Pasteur pipettes and was either tested at once or was filtered on a column of 'Sephadex G-25'. The material appearing in the effluent immediately after the void volume was collected and lyophilized. For testing, the powder was dissolved in fresh culture medium and passed through a Millipore filter (pore size 0.22 μ). In some experiments the supernatant was frozen and was kept at -20° C until used.

Experiments were carried out to test the effect of 5-fluorodeoxyuridine (5FUdr) and puromycin on mixed leucocyte cultures. (5FUdr was a gift from Hoffman-La Roche, Ltd., Montreal, while puromycin dihydrochloride was purchased from Nutritional Biochemicals Corp.). These substances were added at the beginning of the incubation period, in concentrations of 10 and 2.5 μ g/ml., respectively. Media obtained from these cultures and from others to which 5FUdr or puromycin was added at the end of the culture period were filtered on a column of 'Sephadex G-25' lyophilized, and assayed as already described here.

The activity of any given fraction was assessed in terms of its capacity to induce cell transformation in single cultures. Smears prepared from cultures after 5 days of incubation were graded using an arbitrary scale of 0 to + + +. In each experiment every preparation was tested in duplicate or triplicate cultures and smears from some experiments were also scored independently. (We thank Dr. B. Bain, of the Department of Haematology of this Hospital, for examining these slides.)

In six experiments, the extracts of $2-40 \times 10^6$ freshly drawn leucocytes, disrupted by either of the three methods used, gave consistently negative results, whereas strong reactions were obtained using as few as 2×10^6 intact cells (Table 1). Cells heated at 50° C for 5 min also failed to stimulate cells to transform. In contrast to the negative results obtained with freshly drawn disrupted cells, leucocyte cultures (cells and medium) subjected to freezing and thawing after 24 h of incubation gave consistently positive results. Cell-free culture media

removed from leucocyte cultures after 1-5 days of incubation also possessed stimulating capacity.

Media from single cultures were active but were less potent than those obtained from mixed cultures. Media from single cultures added to autologous cells displayed no activity.

Mitogenic activity appeared to accumulate in the culture media; the longer the incubation period, the more activity was recovered. Furthermore, aliquots of fresh culture media put in contact with the same cells on two or three consecutive days each possessed activity.

Since media removed from cultures after incubation possessed activity, experiments where both medium and disrupted cells were assayed together (Table 1) did not disclose whether disrupted cells alone could give rise to blastogenesis. In the following experiment (Table 2) culture media and washed disrupted cells obtained from the same cultures after 4 days of incubation were tested separately. Whereas the media were found to be highly active, the disrupted cells failed to stimulate the target cells to transform. Single cultures from cells of the same donors incubated for 4 days, then washed and mixed, were still able to mount just as strong a reaction as cells mixed at the beginning of the experiment, that is, 4 days previously.

Table 1. STIMULATION OF CELLS IN SINGLE CULTURE BY FRACTIONS OBTAINED FROM CULTURES AFTER DIFFERENT PERIODS OF INCUBATION

Source of mitogenic factor	Incubation before transfer, days	Material transferred	Mitogenic* activity
Single cultures	Nil	2×10^6 intact cells	61/63
Single and mixed cultures	Nil	$2 - 40 \times 10^6$ disrupted cells	0/6
Single culture	Nil	Heated cells 50°C , 5 min	0/2
Mixed cultures	1	Disrupted cells and medium	3/3
Mixed cultures	1-5	Cell-free medium	16/16
Single cultures	4-5	Cell-free medium	3/3† 0/3‡

* The number of positive experiments is given in the numerator; the denominator denotes the total number of experiments performed.

† Transferred to homologous cells.

‡ Transferred to autologous cells.

Table 2. STIMULATION OF CELLS IN SINGLE CULTURE BY CELL-FREE MEDIUM AND DISRUPTED CELLS DERIVED FROM THE SAME CULTURES

Cells incubated	Incubation before transfer, days	Fractions tested*	Reaction	
			A	B
AB	4	Cell-free medium, washed disrupted cells	+++	+++
A	4	Intact cells	0	0
			0	+++

* The cell-free media and disrupted cells tested were derived from the same cultures.

5FUdr and puromycin were each found to inhibit completely the reaction in mixed leucocyte cultures (Table 3) and media from these cultures were also devoid of mitogenic activity. Culture media from cells of the same donors, grown in the absence of inhibitors, tested against the same target cells were fully active. Puromycin or 5FUdr added to these supernatants prior to gel filtration did not abolish the activity, indicating that the lack of demonstrable activity of the media from cultures grown in the presence of the inhibitors was probably not due to a transfer of free inhibitor to the target cells.

The experiments described demonstrate that the factor or factors capable of inducing mitosis of homologous lymphocytes is released by leucocytes in culture. Evidence

Table 3. STIMULATION OF CELLS IN SINGLE CULTURE BY HOMOLOGOUS CELLS OR CELL-FREE MEDIA: THE EFFECT OF INHIBITORS

‡ Puromycin, $2.5 \mu\text{g/ml}$.

§ Control experiments: the inhibitors were added at the end of the culture period prior to gel filtration.

presented indicates that mitogenic activity accumulates in the culture medium; media collected after 3 days of culture possess more activity than that obtained at 2 days which, in turn, is more potent than that collected after incubation for 1 day. Furthermore, aliquots of fresh culture medium put in contact with the same cells on two or three consecutive days each contained activity, indicating that mitogenic activity is released to the medium continuously for at least 4 days.

The mitogenic activity could be due to a preformed factor present in cells and released either continuously or on cell death, or it could be synthesized by the cells during incubation. Failure to find activity after cell disruption by three different methods would make release after cell death unlikely. Indeed, activity could not be recovered from cells disrupted when drawn or after 4 days of incubation. This latter is especially interesting in view of the high levels of activity found in the culture media derived from the same tubes (Table 2). The ability of the cells to elaborate mitogenic activity remained after 4 days of incubation since leucocytes mixed after having been kept in single cultures for 4 days exhibited strong blastogenesis. Finally, freezing and thawing itself would not be expected to deactivate the factor since whole cultures, comprising cells and media subjected to this treatment, yielded activity.

Thus, the experiments described do not support the view that preformed mitogenic factor is present in the cells in concentrations detectable by the methods used. The results presented can be more readily interpreted by assuming that the mitogenic factor is synthesized *in vitro*. This assumption is supported by the results obtained using inhibitors of protein and nucleic acid synthesis; both puromycin and 5FUdr inhibited blastogenesis and media obtained from these cultures were devoid of mitogenic activity. If mitogenic factors were preformed and released from cells during the culture period, then one would have expected to recover activity from these media.

HISTOCHEMISTRY

Fluorochrome Stains for Histological Diagnosis of Visceral Mycoses

FLUORESCENCE microscopy facilitates the demonstration of various fungi in tissues, because it is possible to examine larger parts of the tissue-sections in a short time. Simple stains with fluorochrome dyes—acridine orange, for example—are inadequate for diagnostic use. Two methods which have hitherto been used for the demonstration of polysaccharides proved useful in staining fungi.

(1) Among the fluorescent Schiff-type reagents (Kasten¹) acridine yellow after oxidation with periodic acid gives the brightest fluorescence. The strength of reaction in the different tissue-forms of fungi of importance in Europe is registered in Table 1. A fluorescence not specifically weak appears in the tissue, unless the fraction of the dye is separated in glacial acetic acid. In practice

Table 1

Species and tissue-forms	Periodic acid-acridine yellow	Sulphation-acridine orange ²	Gomori's method
1. <i>Candida</i>			
(a) Budding cells	+++	+++	+++
(b) Pseudohypha	++	+++	+++
(c) Degenerating forms	φ to +	(+) to ++	+ to ++
2. <i>Geotrichum</i>	+ to ++	++	++
3. <i>Cryptococcus</i>			
(a) Capsule	(+) to +	+++	++
(b) Cell-wall	++ to +++	+++	+++
(c) Degenerating forms (without capsule)	φ to +	(+) to ++	++
4. <i>Aspergillus</i>			
(a) Hypha	+++	+++	+++
(b) Degenerating hypha	(+) to +	+ to ++	+++
(c) Conidiophores	+	+++	+++
(d) Spores	φ to (+)	++	++
5. <i>Mucorales</i>			
(a) Hypha	φ	(+)	+ to ++
(b) Spores (only in culture-phase)	φ to +	+++	

Note: (+) = yellow-green to green (colour of the neighbouring tissue).
 +; ++; +++ = Different intensities of yellow or red fluorescence and different intensities of greyish to deep black for Gomori's method.

the tissue-fluorescence disappears if the sections are previously stained with Weigert's iron haematoxylin (cf. Fig. 1).

(2) Fluorochromes, especially acridine orange, are added after sulphation (Moore and Schoenberg²). The fungi show an excellent red-fluorescence (cf. Table 1). In consequence of the low pH, between 2.6 and 2.9, the tissue-fluorescence attains only a green colour (cf. Fig. 2). The fluorescence of the fungi is quickly extinguished on slides that are rich in alkalis; contrary to this, the binding of acridine yellow in the first method is stable.

Fig. 1. Subcutaneous granuloma of candidose in animal-experiment. Periodic acid-acridine yellow technique ($\times c. 850$)

Fig. 2. Human aspergillus-pneumonia. Sulphation-acridine orange technique ($\times c. 300$)

These two methods, especially the sulphation-acridine orange technique, enable a quick diagnosis to be made in frozen sections of fresh tissue. The various tissue forms demonstrated by the morphological methods also provide a rapid guide to the identity of the fungal species³. But other optical methods are by no means superseded, for example, Gram's stain and Ziehl-Neelsen's stain for *Actinomyces* and *Nocardia*, the periodic acid-Schiff technique and Gomori's methenamine silver nitrate. The latter is the most sensitive method for demonstrating details. It impregnates the cell-wall of fungi in progressive degeneration, when other stains fail, and *Mucorales* are best demonstrated by this method. The examination of the sections previously stained according to Gomori is facilitated in polarized light.

IMMUNOLOGY

Antithymic Antibody Localization in the Mouse

ONE of the present-day beliefs is that the thymus is the original source of precursors of the small lymphocyte¹. If this were true, antibody developed against thymus cell antigen might react with cells of the lymphoid series. The purpose of this investigation was to determine whether such antibodies could be developed. The ultimate aim was to explore the usefulness of these antibodies for the depression of the immune response to permit homograft survival either by their use as carriers of large doses of radioactive isotope or by their inherent cytotoxic effect.

Subtotal thymectomy was performed on live mice of the A/J line. The mice were anaesthetized with pentobarbital. The sternum was incised to the level of the xiphoid and a preparatory suture placed to permit rapid closure of the chest. The upper portion of the gland was resected and immediately the suture was closed to prevent pneumothorax. 'Dicrystin' was used to prevent infection.

The microsomal portion of the cell has been reported to contain the most organospecific antigens². The glands were processed so as to isolate this portion as has been described by Nairn³. The nitrogen content was found to be about 50 $\mu\text{g}/\text{ml}$, using the Nessler's reagent method¹.

Male white Dutch rabbits were used for antibody production investigations. The control animal received no injections. The sensitized animal received subcutaneous and intramuscular injections of the microsome preparation accompanied by simultaneous injections of incomplete Freund's adjuvant. Three weeks later, intravenous injections of the same antigen were given with no Freund's adjuvant. At the end of 4 weeks a titre of 1:160 was noted. The microsomal fraction was diluted 1:5 for the microscopic agglutination reaction. Serum-saline and antigen controls were used after incubation in a water bath for 2 h, the tubes were stored at 4° C for 18 h, centrifuged, then viewed.

The crude globulin was purified after the method of Sober⁴. This consisted basically of ammonium sulphate precipitation and chromatographic separation on a column of diethylamino ethyl cellulose. The purified

Fig. 1. Blood clearance of ^{125}I -antithymic antibodies. Slope is 0.004g/h

globulins were labelled with microcurie amounts of iodine-131 (ref. 5). 0.5 ml. of the purified, labelled, antithymic globulin containing 1.87 μc . iodine-131 was injected intravenously into a mouse by way of the eye sinus. The clearance from the blood was determined by means of serial samples from a tail vein into weighed, heparinized capillary tubes. The activity per gram of blood versus time is plotted in Fig. 1.

It was questionable as to whether the counts were localized to any extent on the formed elements of the blood as well as on the serum proteins. To answer this, several samples of blood in heparinized capillary tubes were centrifuged. Each tube was divided into three sections: serum, red blood cells (RBC), and buffy coat (WBC). A comparison was made with a mouse receiving rabbit globulin prepared in the same manner but not immunized against mouse thymus. Using samples collected at 4 h, the results are:

	Immunized globulin Ratio of counts to RBC	Control globulin Ratio of counts to RBC
Serum	26.2	43.0
WBC	19.2	4.4
RBC	1	1

It was also questionable as to whether the high WBC might be due to serum trapped in the buffy coat. Therefore the buffy coat was resuspended in 1.0 ml. physiological saline and allowed to stand overnight at 40° C. Approximately 29 per cent of the counts remained on the WBC. However, much of the count in the serum could have been due to disintegrated white cells or to the release of antibodies previously bound to the lymphocytes. Even with only 29 per cent of the counts definitely associated with the buffy coat, this amounts to approximately 300,000 counts/gram—five times greater than the count for RBC.

72 h following intravenous injection of ^{125}I -labelled globulin, the activity of various organs of the killed mouse was determined. These values are reported as a fraction of the activity in the peripheral blood.

Because iodinated serum albumin (human) (RISA) does not leave the blood stream significantly in 10 min, values obtained by using RISA and otherwise performing the experiment in the same manner represent activity due to blood supply alone. The ratio formed by the uptake of ^{125}I -labelled globulin and uptake of RISA indicates the specificity of the various body tissues for the antibody. The results appear in Table 1.

The differential localization of tagged γ -globulin indicates that the prepared antibody is most specific for the thymus gland. However, lymph nodes, bone, striated muscle, and the GI tract have significant localization. The lymphatic tissue in the lymph nodes and in the GI tract is probably the area where the activity is centralized in these two organs. The relatively high concentration

	Table 1				Ratio Column (2) Column (4)
	^{125}I -labelled globulin (1) Counts/g/ min	Fraction of the counts/g/min for blood (2)	(3) Counts/g/ min	RISA (4) Fraction of the counts/g/min for blood	
Blood	104,460	1.00	88,130	1.000	1.00
Thymus	34,220	0.328	8,200	0.093	3.52
Striated muscle	7,690	0.074	2,430	0.028	2.67
GI	10,530	0.101	1,720	0.053	1.89
Bone (sternum)	13,600	0.130	6,156	0.070	1.86
Lymph node	30,580	0.293	14,250	0.162	1.81
Lung	35,810	0.343	26,760	0.304	1.13
Kidney	27,140	0.260	24,454	0.278	0.94
Liver	22,230	0.213	22,790	0.258	0.82
Spleen	19,995	0.124	13,770	0.156	0.80

of radioactivity in the bone may be due to common antigenicity between the reticulum cells in bone and lymphoid tissue. The relative specificity for muscle is difficult to understand. However, the simultaneous presence of thymoma and myasthenia gravis and the suspicion that this latter disease has an antigen-antibody aetiology make one wonder if this muscle specificity might not be meaningful. The counts/g of muscle are very low for labelled globulin and RISA, but the ratio of these activities indicates uptake in excess of that attributable to blood supply alone. The failure of specific uptake of antibody by the spleen is most puzzling. The presence of considerable activity in the buffy coat of centrifuged blood indicates that the antibody does have some affinity for circulating lymphocytes—as was previously postulated.

The slow clearance of antibody from the blood makes it undesirable to depress the antibody-producing system by means of radioactivity tagging, since this becomes tantamount to utilizing external, whole-body radiation. Another approach would be to inject a relatively large amount of unlabelled antibody. The idea behind this scheme is that cells to which antibody adheres might be rendered non-functional. Thus, with preferential localization of the antibody or lymphatic cells the rejection response of the host to a homologous graft might be suppressed.

Isoprecipitin in the Sera of Rats resistant to Tumour Transplantation

REJECTION of transplanted tumour cells is one of the most important phenomena for understanding the immunology of cancer, but the appearance of precipitin in the sera of recipient animals has not yet been clearly demonstrated. I have recently detected explicit isoprecipitin in the sera of rats with acquired resistance to transplantation of Yoshida ascites hepatoma cells, AH49.

A high percentage of rats accept the transplanted Yoshida ascites hepatoma when inoculated with a sufficient number of the hepatoma cells. For example, in the case of AH49 strain of the ascites hepatoma, 10^7 cells are sufficient to produce more than 90 per cent successful transplantation. However, for an unknown reason, some rats reject the transplantation. These resistant rats, usually, do not take the same cells again by repeated transplantation.

The sera of these resistant rats were examined for the precipitin reaction to an antigen isolated from the cancer cells. A fraction referred to as S_5 -protein was extracted from homogenates of the ascites hepatoma cells at pH 4.8 with acetate buffer, 0.1 M, as previously reported^{1,2}. This fraction contains cancer specific antigenic protein(s) as examined by precipitin reaction with rabbit antisera against S_5 -protein. The specific protein(s) was partially purified by ion exchange cellulose chromatography³. The purification was also carried out by combination of ammonium sulphate fractionation and a zinc ion precipitation reaction. This procedure gave a purified protein material referred to as 6P-fraction (unpublished data).

A strain of Yoshida ascites hepatoma⁴, AH49, which was originally developed in the livers of Japanese hybrid rats by feeding with *p*-dimethylamino-azo-benzene, was used in this investigation. Average survival time of the rats transplanted with these cancer cells is 7–9 days. The tumour cells of this strain were transplanted into Japanese hybrid rats. The rats which rejected the transplants were inoculated with the same cells repeatedly at intervals of two weeks.

The precipitin reactions of the sera of resistant rats were examined either by the ordinary ring test or by the agar diffusion technique.

Some experimental results are presented in the accompanying tables and photographs. As seen in Table 1, resistant rats which were inoculated with AH49 cells twice or more (at two-week intervals) showed, without exception, positive precipitin reactions. A negative reaction was seen in 75 per cent of rats inoculated only once.

Table 1. PRECIPITIN REACTION OF RESISTANT RAT SERA

No. of inoculation*	No. of rats tested	Titre of precipitin† (two-fold dilution)	Positive reaction‡
1	12	0–32	3/12 (25%)
2	8	16–64	8/8 (100%)
3	8	16–64	8/8 (100%)
4	4	16–128	4/4 (100%)
5	6	32–64	6/6 (100%)
6	6	16–128	6/6 (100%)
7	14	16–256	14/14 (100%)
9	12	32–128	12/12 (100%)
11	10	32–128	10/10 (100%)

S_5 -protein or a purified material, 6P-protein, of AH49 cells was used as antigen of the precipitin reaction.

* Approximately 2×10^7 cells of AH49 hepatoma were inoculated intraperitoneally every two weeks.

† Titration by the ring test.

‡ Positive precipitin reaction tested by the agar diffusion technique.

The reaction was never demonstrated in the sera either of normal rats or of tumour-bearing rats as shown in Table 2.

The antisera reacted specifically with the proteins (S_5 -protein or 6P-protein) of AH49 hepatoma cells only, but not with the protein fractions of various normal

Table 2. PRECIPITIN REACTION OF THE SERA OF RATS WITH OR WITHOUT TUMOUR

	No. of rats	No. of rats of positive precipitin reaction*	Percentage
Normal rats	50	0	0
Tumour-bearing rats†	49	0	0
Resistant rats‡	80	71	90

* By the agar diffusion technique.

† AH49 ascites hepatoma-bearing rats.

‡ Resistant to AH49 hepatoma cell transplantation.

rat tissues or with the proteins of other strains of Yoshida ascites hepatoma, for example, AH66, AH127, AH41B, AH131B, etc. The reaction was highly specific.

Antibody titres examined by the two-fold dilution method of the antisera were 0–256 times dilution depending on the number of inoculations.

Immunoelectrophoretic analyses revealed that the precipitin is located in the region of γ -globulin fraction of the antisera. Electrophoresis of the rat sera indicated that the γ -globulin fraction of the resistant rats increased remarkably while that of tumour-bearing rats decreased drastically.

Fig. 2. Precipitin reaction of rat sera: N5, serum of resistant rat No. 5 inoculated with AH49 cells five times; P-36, serum of an AH49 ascites hepatoma-bearing rat; L5, as in Fig. 1; 49-S5, as in Fig. 1; 49-6P, purified antigenic protein from S_5 -protein of AH49 cells; 41B-S5, S_5 -protein fraction isolated from AH41B cells; 127-S5, S_5 -protein fraction isolated from AH127 cells.

Thus, the isoprecipitin reaction in the sera of resistant rats suggests an intimate connexion with the antitransplantation phenomenon. However, the essential role of isoprecipitin in development of the antitransplantation mechanism is still obscure. AH49 cells were originally developed in the Japanese hybrid rats as previously mentioned. In the present study this strain of hepatoma was transplanted to the hybrid rats. Results obtained in isologous and autologous system may differ. The immunogenetic relation between host and transplant is under investigation.

PATHOLOGY

Inhibition of Growth of Malignant Cells *in vitro* by a Component of Normal Adult Connective Tissue

NUMEROUS reports during the past 30 years support the thesis that biologically active factors present in normal adult tissue, growth-stimulating and growth-inhibiting substances, form a complex which regulates the growth of normal adult tissue. Upset of this balance may result in the unrestrained growth of cancer¹⁻⁷. We have described the extraction by mild tryptic digestion of constituents of normal adult connective tissue (aorta, tendon, and skeletal muscle) which were growth-stimulating or growth-inhibitory to normal fibroblasts in tissue culture⁸. The effect on growth *in vitro* varied according to the conditions of extraction. Inhibitory extracts and crude precipitates from them further inhibited the growth in primary tissue culture of a series of human tumours from 75 to 100 per cent (refs. 9, 10).

It seemed of interest to determine whether results obtained with established strains of malignant cells would correlate with those from tests of fresh tumour tissues. An attempt was also made to separate, by DEAE-cellulose chromatography, material from the crude preparations which would inhibit specifically different types of tumour cells. During the past two years we have tested the effect of extracts, fractions, and DEAE-cellulose sub-fractions on the following strains of normal and malignant tissue in culture: short-term strains of two tumours carried for many years in animals, the Rous chicken sarcoma, and a human sarcoma, *H.S.1* of Toolan-Fjelde^{11,12}; three strains of normal human fibroblasts and two strains of highly malignant epithelium, a 12-year-old strain of human epidermoid carcinoma of the larynx, *H.Ep.2* of Toolan-Fjelde^{11,12}, and a 5-year-old strain of human grade III serous cystadenocarcinoma of the ovary isolated at this institution, *J.M.*¹³. Fractions were obtained which were 100 per cent inhibitory to the cells of the Rous sarcoma and to *H.S.1*, but had little or no effect on the normal fibroblasts¹⁴. Many fractions were isolated which were markedly inhibitory to the young strain, *J.M.*, but had no effect on the older epithelial strain, *H.Ep.2*¹⁴. This report deals with the effect of DEAE-cellulose chromatography sub-fractions on the growth *in vitro* of the *J.M.* strain of ovarian tumour cells.

Crude inhibitory extracts were prepared from chicken skeletal muscle or beef tendon by mild tryptic digestion under conditions which had previously been found to be optimal for the extraction of inhibitors⁸⁻¹⁰. The inhibitory factors were precipitated by ethyl alcohol and CaCl_2 as described previously¹⁰. These precipitates were fractionated on 2×80 cm columns of DEAE-cellulose equilibrated with phosphate buffer 0.005 M, pH 8.4. In one typical run, 140 mg of the ethanol precipitate was applied to the column, in another, 220 mg of the CaCl_2 precipitate. A pH and ionic strength gradient was established to pH 6, 0.1 M and 2 M NaCl. 6-ml. fractions were collected and combined according to the ultra-violet patterns.

The cell strains were maintained as a monolayer on glass in milk dilution bottles in a medium of 25 per cent mixed horse and human placental serum in Parker's medium 199 at pH 7.2. For tests for effect on growth of cells in tissue culture, dense bottle growths of cells were brought into suspension by trypsinization, the cells were counted in a haemocytometer, suspended in fresh medium and distributed to Carrel flasks or Leighton tubes in 1-ml. lots containing two hundred thousand cells. In two to three days, when the cells had formed uniform sheets, the medium was replaced with 10 per cent serum in the inhibitory extracts. In each experiment, there were two controls of 10 per cent serum in Moscona solution. After two days' incubation the cells in one flask were

Figs. 1-4. Photomicrographs of cultures of serous cystadenocarcinoma of the ovary (*J.M.*). Figs. 1 and 2, sister cultures; Fig. 1, in control medium, 10 per cent serum in balanced salt solution; Fig. 2, in 10 per cent serum in crude inhibitory extract from skeletal muscle; Figs. 3 and 4, sister cultures; Fig. 3, in control medium, 10 per cent serum in balanced salt solution; Fig. 4, in 10 per cent serum in inhibitory fraction separated by DEAE-cellulose chromatography from the crude extract in Fig. 2. (Giemsa $\times 50$)

counted and duplicate flasks were stained for microscopic observation.

Crude extracts, alcohol and CaCl_2 precipitates and DEAE-cellulose fractions eluted at high ionic strength all had a markedly inhibitory effect on the cells of the highly malignant cystadenocarcinoma of the ovary. Figs. 1 and 2 show the destructive effect on these cells of the crude muscle preparation described above. DEAE-cellulose chromatography of precipitates derived from either skeletal muscle or tendon yielded ultra-violet absorbing peaks at about pH 6 and relatively low ionic strength with no effect on growth or mildly stimulating to these cells. On the other hand, material more strongly adsorbed on the column and therefore eluted at later stages at a lower pH, 4.5, and high ionic strength, 1-2 M NaCl, inhibited growth. These sub-fractions have repeatedly reduced the number of cells countable in tissue culture by 75-100 per cent. Such cells as remain in the preparations appear to be completely degenerate in the histological preparations. Figs. 3 and 4 show the destructive effect of the inhibitory DEAE-cellulose fraction prepared from the crude extract on the same cystadenocarcinoma cells. The factors had relatively little effect against the cells of the human epidermoid carcinoma of the larynx, *H.Ep.2*.

These growth inhibitors, which are components of normal adult connective tissue, are highly active biologically, since very small amounts by weight, 0.05 mg/ml. or less, clearly show the effects described. The chemical nature of the inhibitors has not as yet been determined. We have strong indications that several chemically distinct factors are involved, differing in resistance to heat and dialysis. The major component appears to be non-dialysable and resistant to 58°C. Nitrogen values indicate about 50 per cent protein. There is no DNA present, but approximately 10 per cent RNA. Organically bound sulphate is detectable, but sensitive tests failed to reveal significant amounts of hexoses, hexosamines or hexuronic acids¹⁵. In addition, there is at least one dialysable component which contributes to the observed activity. It appears to be a peptide or conjugated peptide associated with RNA but free of hexose or hexosamine.

We thank Mrs. Lillian Adams, who developed the strain of ovarian cancer cells for our original stock, and Mrs. Grace Lien Lew and Miss Tess Kourkouvelis for their help. This investigation was supported by Public Health research grant CA-04870 from the National Cancer Institute, and institutional grants from the American Cancer Society.

area heavily infested with pigeons. One of the three samples originated from a thick layer of dry undisturbed pigeon droppings. The other two positive samples were taken from a layer of dark dust on the wall ledges of the church.

This finding of virulent strains of *C. neoformans* from pigeon manure confirms the view of Emmons⁵ that the association between virulent *C. neoformans* strains and pigeon excreta is not an unusual or geographically restricted phenomenon.

BIOLOGY

Activation of Spores of *Penicillium roqueforti*

GERMINATION of fungal spores is characterized physiologically by transformation of the spore from a dormant state of low activity to a state of high metabolic activity, and morphologically at a later stage by swelling of the spore and production of a germ tube. Since activation, that is, the termination of the dormancy of the spore, is the initial stage of germination, an examination of the activation process itself makes a logical starting point to the study of the biochemical aspects of germination. This communication describes the effect of different physiological agents on the ability of spores of *Penicillium roqueforti* to oxidize octanoic acid and hence provides a method of assessing the influence of these agents on activation. The method may also be applicable for studies of the effects of these agents on the subsequent stages of the germination process.

Spores of *P. roqueforti*, strain 6989, obtained from the American Type Culture Collection, Washington, were grown on slopes of Czapek-Dox agar (Oxoid) at 22°. After 6-10 days' incubation the spores were collected by adding distilled water and carefully scraping them from the surface of the slope with a sterile needle. They were separated from small pieces of agar and mycelium by filtering the suspension through two layers of cheesecloth. The spores were then collected on a 'Millipore' filter, washed with distilled water and transferred to M/10 sodium phosphate buffer. The suspension so obtained was standardized in a haemocytometer to give a final concentration of 0.5×10^8 spores per ml. For every 15 ml. spore suspension 10 mg streptomycin were added in order to minimize growth of contaminating bacteria¹. The progress of oxidation of fatty acids (3 μ moles) was followed manometrically at 27° in a standard Warburg apparatus, 0.2 ml. 20 per cent KOH being used in the inner cell. The methyl ketone concentration was determined at intervals during the experiments by pipetting 1 ml. of the contents of the Warburg flask into 1 ml. of 2,4-dinitrophenyl hydrazine (2 g/litre 2 N HCl) in a stoppered test-tube and the 2,4-dinitrophenyl hydrazones estimated by the procedure outlined by Lawrence².

Preliminary work showed that although washed spores of *P. roqueforti* could oxidize fatty acids only extremely slowly, the addition of glucose or 'Bacto' casamino acid solution (Difco) dramatically increased both oxygen uptake (Fig. 1) and methyl ketone formation after an initial lag period of 1-2 h (Fig. 2). A subsequent decrease in rate of oxygen uptake and methyl ketone formation indicated the completion of fatty acid utilization. The striking preferential utilization of a small amount of fatty acid (3 μ moles) in the presence of a large excess of sugars

Isolation of *Cryptococcus neoformans* from Pigeon Habitats in London

FROM the several cases of human cryptococcosis (torulosis or European blastomycosis) reported from Great Britain it is apparent that this is not an uncommon mycosis in this part of the world. Recently, Rook and Woods¹ listed twenty-two cases of the disease recorded in Britain. There does not appear to have been any published information, however, on the saprophytic habits of the causative fungus (*Cryptococcus neoformans*) in Britain. The following is a report on the isolation of *C. neoformans* from pigeon habitats in London, a preliminary notification of which was made at the International Academy of Pathology Symposium on Mycotic Diseases (June 1964) by one of us (R. W. R.).

Samples of pigeon manure from the concrete floors, walls and window-ledges of buildings inhabited by pigeons, and of soil from localities frequented by pigeons, were collected from four areas in west-central and one area in south-west London. These were examined for the presence of *C. neoformans* by suspending the samples in sterile normal saline, the supernatant being cultured on Sabouraud's dextrose agar containing chloramphenicol. Incubation was at 37° C, a temperature which inhibits many of the saprophytic moulds and yeasts. Identification of the yeasts isolated was based on methods described by Lodder and Kreger van Rij². In addition, biochemical properties included a positive urease test³ and the ability to assimilate creatinine⁴. Pathogenicity of the *C. neoformans* strains isolated was shown by animal inoculation tests using white mice. The results of 49 samples of pigeon manure and soil examined are given in Table 1. All the three positive manure samples came from the yard of a well-known west-central London church sited in an

Table 1. RECOVERY OF *C. neoformans* FROM PIGEON HABITATS

Sample	No. examined	No. positive

(250 μ moles) and of amino-acids (between 100 and 1,000 μ moles) is consistent with the finding of Farkas and Ledingham³ that uredospores of wheat stem rust preferentially use fatty acids as respiratory substrates.

The formation of 2-heptanone from octanoic acid was almost independent of pH between pH 4.5 and 7 (unpublished results), the limits of pH for optimum fungal spore germination⁴. Between 60 and 70 per cent of the acid was ultimately oxidized to 2-heptanone after 3–6 h incubation with the stimulating agents. The activated spores, on microscopic examination, were found to be apparently unchanged morphologically. Similarly, with spores of *Penicillium chrysogenum*, increases in total nitrogen, protein, RNA and the rate of oxygen uptake were noted about 7 h before the appearance of germ tubes⁵.

To confirm that the stimulatory effect of casamino acids resulted from the influence of one or more amino-acids, the effect of individual amino-acids on the ability of the spores to oxidize octanoic acid was tested. An increasingly pronounced stimulatory effect was associated with the following amino-acids, used at a concentration of 100 μ moles/3 ml.: L-leucine, L-arginine, β -alanine, α -aminobutyric acid, γ -aminobutyric acid, L-glutamine, L-proline, L-serine, D-alanine, L-alanine. No individual amino-acid was as effective as either casamino acids (0.1 g/3 ml.) or glucose (250 μ moles/3 ml.) (Fig. 2). Aspartic acid, asparagine, glycine, threonine, isoleucine, tryptophan, and tyrosine had no effect, while cysteine, histidine, methionine, valine and glutamic acid retarded formation of 2-heptanone from octanoic acid.

Of the monosaccharides tested for their ability to stimulate the oxidation of octanoic acid by spores, D-xylose at a concentration of 250 μ moles/3 ml. was the most active, although D-glucose and D-galactose were

Fig. 1. The effect of octanoic acid (Δ - Δ), glucose (\square - \square), glucose plus octanoic acid (\circ - \circ), casamino acids (\blacksquare - \blacksquare), and casamino acids plus octanoic acid (\bullet - \bullet) on the oxygen uptake of washed 7-day-old spores (1.5×10^8) in phosphate buffer, pH 6.5 (100 μ moles). 250 μ moles glucose, 0.05 g casamino acids and 3 μ moles octanoic acid were used. Total volume 3 ml.

Fig. 2. The effect of amino-acids (100 μ moles), casamino acids (0.05 g) and glucose (250 μ moles) on the formation of 2-heptanone from octanoic acid (3 μ moles) by washed 7-day-old spores (1.5×10^8) in pH 6.5 phosphate buffer (100 μ moles). Total volume 3 ml.

Fig. 3. The effect of sugars (250 μ moles) on the formation of 2-heptanone from octanoic acid (3 μ moles) by washed 7-day-old spores (1.5×10^8) in pH 6.5 phosphate buffer (100 μ moles). Total volume 3 ml.

almost as efficient. The spatial configuration around carbon atoms 1, 2 and 3 is the same in these 3 sugars. D-mannose, D-fructose, L-sorbose, D-arabinose, D-sorbitol and L-rhamnose were less stimulatory (Fig. 3). Galactitol, D-mannitol, D-ribose, D-lyxose, D-tagatose, D-glucuronic acid and D-glucosamine were almost without effect. It would appear therefore that some sugars are metabolized more readily than others to yield either energy or metabolic products essential for the activation process, and that the spatial arrangement of H atoms and —OH groups around the carbon atoms in the sugars may have special significance.

Of the oligosaccharides examined, only sucrose was as stimulatory as glucose. Maltose, trehalose, cellobiose and melezitose had a slight stimulative effect, whereas lactose and melibiose had no effect. Other compounds found to have no stimulatory effect were adenosine, adenosine triphosphate, inosine, adenine, glyceraldehyde, glycerol, pyruvate, citrate, succinate, malate, lactate, ethanol and propionate.

The specificity of the stimulatory agents suggests that their metabolism may provide an insight into the overall termination of dormancy. Results to be published in detail elsewhere suggest that their role is connected with the transport of fatty acid across the cell wall and that the effect being measured in these experiments is, in part, the stimulation of transport of octanoic acid into the cell. Suitable biosynthetic conditions are needed for the development of transport mechanisms which in turn regulate the entry into the cell of specific substances⁶. The lag period observed with washed spores could also be a result of the need for induced enzyme synthesis (for example, of β -keto acid decarboxylase) or a change in permeability. Levinson and Hyatt⁷ have suggested that the prime event in germination is a breach of a permeability barrier. Whatever the actual mechanism, however, the formation of methyl ketone would still provide a reliable measure of whether or not the spores had been activated.

In the comparatively few studies that have been carried out to determine the effect of different physiological agents on fungal spore germination, various criteria have been used to distinguish germinated from non-germinated spores; for example, the swelling of spores¹ and the proportion of spores that form a germ tube in a given time⁸. Such criteria, however, are somewhat subjective in nature and difficult to measure in practice. The marked similarity between the agents that stimulate the oxidation of octanoic acid by spores and those, in particular glucose, *l*-proline and *l*-alanine, that have been reported to stimulate the germination of fungal spores^{1,9,10} suggests that some reactions are common to both. Since Franke and Heinen¹¹ have shown that 30 out of 38 fungi tested were able to form methyl ketones from fatty acids, the utilization of this property to indicate which compounds are likely to stimulate germination of non-activated spores might have wide application.

Warted Pollen Grains of the Epacridaceae

WATSON¹ has directed attention to the ektexine ornamentation of pollen grains in the genus *Styphelia* Sm. Ten species were available for examination and their pollen grains bore curious warts.

An examination of the pollen of another genus of the Epacridaceae has shown that some species of *Epacris* Frost. et. f. emend. Cav. also have grains with warts or papillae.

Australian botanists generally agree that the classification of *Epacris* requires revision. A list of species at present acceptable has been drawn up on the advice of

taxonomists in Australia. The species are given in Table 1, with the exception of *Epacris barbata* Melville, *E. petrophila* Hook. and *E. sparsa* R. Br. It has not yet been possible to examine the pollen of the three latter species.

The *Epacris* pollen was examined after acetolysis. The papillae appear in general to be more closely placed on the grains than those noted for *Styphelia*². The warts tend to become detached from the pollen grains (cf. *Styphelia*) and it is possible that acetolysis has removed these features from some grains.

The warts vary from 1 to 10 μ in diameter between the species. There is also variation within the species. The

Fig. 1. *Epacris rigida* tangential section

Fig. 2. *Epacris rigida* optical section

diameter of warts on one grain of *Epacris rigida* was observed to vary between 2 and 10 μ .

It would be premature to assess the significance of warts or papillae for the classification of *Epacris*, but there can be no doubt that the presence or absence of these structures will be an aid to further systematic investigation.

The assistance of Dr. N. T. Burbidge, C.S.I.R.O. Division of Plant Industry, Canberra; Mr. J. Willis, the National Herbarium, Melbourne; and Mrs. P. Walker, the Department of Botany, the Australian National University, Canberra, in the selection of acceptable species of *Epacris* is gratefully acknowledged.

Relationships between Constituents of Cones and Male Flowers of the Hop (*Humulus lupulus*, L.)

Hop breeding is complicated by the fact that the flowers of male plants are useless for breeding, so that their genotype in this respect cannot be indicated phenotypically. Hence male parents for breeding work have hitherto had to be selected by progeny testing. Brewing quality of hop cones (the female inflorescences) depends mainly on the amounts of soft resins present (the α -acid fraction being the most important) and the composition of the essential oil. The resins produce the bitter character of beer, while the oils contribute the characteristic flavour.

Brooks and Likens¹ have analysed the soft resins in the flowers of 20 male clones and demonstrated significant genotypic differences between them. They have not yet demonstrated that the resin characteristics of these males are transmitted to their progeny.

Using gas chromatographic methods, Roberts² analysed the essential oils in the cones of female, and flowers of male, plants and found that in a seedling family the characteristics of both parents reappeared among the progeny. Tetraploid hop plants with XXXY sex chromosomes are monoecious and both sexes are fertile, so such plants can be selected for the brewing quality of their cones and then used as pollen parents in a breeding programme³. Such plants also offer a means of determining whether cones and male flowers on the same plant and, therefore, genotypically identical give comparable results when analysed for resins and essential oils, or whether there are fundamental differences between them.

During the 1964 season, resin and essential oil analyses were carried out on cones and male flowers of 16 tetraploid monoecious plants, the resin determinations being of α -acid (a mixture of humulone and analogues) and of total soft resin (the resin fraction soluble in paraffinic hydrocarbons, ether and methanol and determined by solvent extraction). The difference between these values is referred to as the β -resin. The β -acid contents of both sexes were determined by similar polarimetric methods using ether extraction⁴. The mean value for α -acid content in the cones was 13.0 times that for the male flowers, but there was a significant correlation between the two sets of values ($P < 0.01$). The β -resin content in the cones was only 5.9 times that for the male flowers and there was no significant correlation between these values. As shown in Table 1, the α -acid β -resin ratio was higher in the cones than in the male flowers; very similar results were obtained from analyses on male and female plants from two normal seedling families. As β -resin is an imprecisely defined mixture, it is possible there is a component that is abundant in male flowers which is absent or present only in small amounts in cones.

Table 1. MEAN VALUES FOR α -ACID AND β -RESIN CONTENTS IN CONES AND MALE FLOWERS OF TETRAPLOID MONOECIOUS PLANTS AND DIPLOID SEEDLING FAMILIES

	Sex	α -Acid content %	β -Resin content %	Ratio α -acid/ β -resin

Dioecious family 21/62	Female	4.08	9.31	0.44
	Male	0.14	0.90	0.15

The essential oil compositions of both cones and male flowers of the monoecious plants were determined by ether extraction (room temperature) of the dried flowers (0.5 g) and evaporation of the dried solution on to 'Celite' at room temperature, followed by gas chromatography of the 'Celite' sample². Myrcene, caryophyllene, humulene and sometimes farnesene (depending on variety) are the major oil components in cones, but myrcene does not show up by this technique. In all cases the cones and male flowers from the same plant gave similar proportions of caryophyllene and humulene. Two plants contained farnesene in the cones, but no male flowers contained measurable quantities of this compound. All the male flowers contained at least one extra component that was absent from the cones (Fig. 1).

Fig. 1. Chromatograms of (a) male flowers and (b) cones from the monoecious plant 25/57/84. (Pye Argon chromatograph, 4 ft. column of 10 per cent 'Apiezon L' on 60-80 mesh 'Celite', 175° C, rate of flow 60 ml/min)

The differences noted between cones and male flowers of tetraploid monoecious plants have also been found between male and female diploid plants. In one seedling family, large farnesene peaks were present in all 15 female seedlings examined. In other families farnesene was present in some females but absent from others. None of the male seedlings examined showed definite farnesene peaks, nor did the male parents, although some transmitted this character to their female progeny. The ratios obtained suggest that the presence of farnesene is a sex-limited character controlled by a single pair of genes with presence of farnesene dominant to absence. The unidentified peak found only in the male flowers of monoecious plants was characteristic of all diploid male plants examined, but was absent from diploid females. Preliminary evidence indicates that another component (probably selinene) which is abundant in some females may be much less abundant or absent in males.

This work has clearly indicated that there are fundamental differences between the essential oils and resins of cones and male flowers, and the same differences are found whether these are on separate dioecious plants or occur together on monoecious plants. Since there was a correlation between the α -acid contents of cones and male flowers on monoecious plants, it is probable that α -acid determina-

tions on male plants will be a valid method of selecting them for breeding purposes.

Radiation-induced Sex Reversal in *Ecballium elaterium*

Galán^{1,2}, whose work was reviewed by Mather³, showed that the cucurbitous plant *Ecballium elaterium* has been shown to exhibit the simplest sex-determining mechanism ever found in higher plants. A dioecious variety growing in the south of Spain and in North Africa maintains a 50 per cent pro-sex ratio in Nature by means of a pair of alleles $a^D > a^d$. Male plants are heterozygous while female ones are recessive. On the other hand, the well-known monoecious variety which grows in Mediterranean Europe is homozygous in a third allele a^+ . Through reciprocal hybridization between both varieties, Galán was able to demonstrate that allele a^+ dominates a^d , but behaves as a recessive factor in relation to a^D .

During the past three years we have attempted to induce mutations in the allelic series $a^D > a^+ > a^d$, especially in the two alleles which are involved in the dioecious variety. Gamma rays, neutrons and diethyl sulphate (DES) have been used as mutagenic agents. Our tests in the first year recommended a dose of approximately 20,000 rads of ionizing radiation for treatment of dry seeds. DES was used at a concentration of 1/500 during 24 h. Chronic gamma irradiation of growing plants was also carried out with dose rates ranging from 10 to 120 rads per day. Neutron exposures were delivered at the J.E.N. nuclear reactor of La Moncloa (Madrid) while gamma rays were provided by our own gamma facility ('El Encin', Alcalá de Henares) equipped with a 2,250-c. Cs-¹³⁷Ba source.

However chronic or acute was the treatment, notes were only taken of the actually irradiated generation (R_1), since it can easily be learned that mutations $a^D \rightleftharpoons a^d$ in any direction would show up readily from genotypes as $a^D a^d$ or $a^+ a^d$, with no need for back-crossing. Nearly 2,000 mature individuals were observed in each of their branches, for in irradiated seeds an induced mutation would normally affect a single cell in the embryo, and it would only appear partially in the adult plant.

In the course of three seasons we have been able to observe a number of sex aberrations which were clearly not mutations but probably originated from disturbances in the mechanisms concerned in sex phenotypic expression. Some new characters not affecting sex also appeared, a few of them probably genetic changes. These are now being observed for a future tentative list of mutable genes in this interesting plant species.

Late in summer 1964, one instance of a sex reversal with a high probability of being of genetic origin, was detected in a masculine plant of the dioecious variety, arising from a neutron-irradiated seed. It consisted of a complete reversal to morphologically quite normal female flowers, affecting one of the lower branches of the plant; moreover, it did not involve the whole branch but certain nodes of it. After a detailed phyllotactic map was built, the new character appeared to be distributed clearly in a sector of approximately 180 degrees. Sectoriality strongly suggests that we are dealing with a mutation, at least in the wider sense of this word that includes chromosome deletions or re-arrangements.

No other character was observed to change in association with the flower sex. Leaf and stem colour, leaf shape, hair pattern, etc., were unaltered. Curiously, it was the fact that while flower morphogenesis reached a quite reversed expression, the aspect of the inflorescence remained essentially masculine. In the leaf axil of a male plant of *E. elaterium* var. *dioicum*, the inflorescence is elongated and bears up to 15-20 flowers successively during the season (see Fig. 1, upper left); the first of these flowers originates from a different primordium and bears no bract, though its peduncle is largely connated to the inflorescence axis⁴. This first flower is the only one which develops in the axil of female plants, of course with a female expression⁴. In this case, after fecundation, the stalk thickens and elongates rapidly, with a marked negative geotropism (upper right); the fruit at its top explodes later by the well-known hydraulic seed dispersal mechanism of this species. On our mutated branch, female flowers were found not only in the axil, but also rather clustering along non-thickened, non-geotropic axes (lower figure, on the right).

Fig. 1

Unfortunately, female flowers of the reversed branch yielded only three or four poor-looking seeds which would probably be unable to germinate, and in any case would not provide enough information on sex proportions in the R_2 . Many of these flowers gave rise to well-developed though seedless fruits, or in other words, to parthenocarpic fruits. The observed sterility may be the consequence of an induced chromosome aberration, perhaps a deletion involving gene a^D . Lack of apparent side effects on the phenotype would seem to indicate that the hypothetical chromosomal damage is not too drastic. The possibility still remains of a mutation $a^D \rightarrow a^d$ where the female genotype loses most of its fertility within a 'male environment'.

Ingestion of Soil by Sheep in New Zealand in Relation to Wear of Teeth

In certain parts of New Zealand, excessive wear occurs in the incisor teeth of sheep, with the result that sheep must be culled from flocks at a comparatively early age, because they are no longer able to graze efficiently.

It has been proposed that constituents of actively metabolizing herbage which predispose sheep's teeth to excessive wear appear to be: (1) enzymes (proteinases), which attack the organic bonding material of the dentine; (2) acids which chelate calcium of the apatite. By these agencies tooth structure may become weakened and susceptible to attrition by the tougher constituents of the herbage such as fibre and plant phytoliths¹. Wear has been attributed by Australian workers to abrasion by plant phytoliths^{2,3}.

The investigation reported in part here arose from a survey into wear by J. Wellington, Department of Agriculture, and was undertaken to assess the relative importance of physical and chemical factors that might be responsible for differences in wear noted in sheep on selected farms on different soils in the Wairarapa area of the North Island.

Farm A. High level of wear in sheep's teeth. High production ryegrass clover pasture. Yellow-grey earth soil (Wharekaka silt loam).

Farm B. Medium level of wear in sheep's teeth. High production ryegrass clover pasture. Yellow-brown loam soil (Tauherenikau stony loam).

Farm C. Low level of wear in sheep's teeth. Low production, unimproved pasture with high proportion of native grasses and moss. Steepland soil (Ruahine steep-land soil).

As part of the investigation into physical and chemical factors, analysis of sheep faeces was carried out to measure the amounts of soil taken in with pasture by the grazing animal, since soil could be an important factor in any abrasive process. The data for soil ingested over the winter months are of special interest.

Faeces samples were collected at approximately three-weekly intervals from July to December on the three farms. Only fresh faeces were collected and particular care was taken to collect pellets or stool material not in contact with pasture or soil. For each sample on each farm approximately 5 g of fresh faeces was collected from each of 40 separate piles of faeces, to give a composite sample of about 200 g. The whole sample was dried, ashed at 550° C and extracted with successive portions of 3 N hydrochloric acid to yield an acid-insoluble residue. Comparison of faeces samples collected in this way with faeces samples taken direct from the rectum of sheep grazing the same pasture shows close agreement in acid-insoluble residue figures. In Table 1 the acid-insoluble residue levels for the period July–December are expressed as a percentage of faeces on a dry matter basis (100° C). For the purpose of calculating weight of soil ingested per day it has been assumed that dry matter intake is at a level of 1 kg per day and that the ratio of dry matter faeces : dry matter pasture is 1 : 6. If dry matter intake of pasture per day is less than 1 kg per day, soil ingestion figures will be correspondingly reduced; if the ratio of dry matter faeces : dry matter pasture is greater than 1 : 6, soil ingestion figures will be increased. It is estimated that at a dry matter intake of 1 kg per day approximately 15 g of the acid-insoluble residue per day will come from the pasture, probably mostly in the form of plant phytoliths. This figure has been subtracted from the daily total of acid-insoluble residue to give a net figure which is taken to be ingested soil—this has been confirmed by the presence of quartz peaks in X-ray diffraction studies of the acid-insoluble residue. The results are presented in Fig. 1 on this basis.

It can be seen that soil ingestion is high over the wet winter period on the 'high-wear' farm, Farm A, when

Table 1. ACID-INSOLUBLE RESIDUE IN FAECES (Per cent dry matter)

Period of collection	Farm A (high wear)	Farm B (medium wear)	Farm C (low wear)
July 14, 1964	45.9	34.2	9.5
July 24–30, 1964	44.4	25.3	9.4
Aug. 18–19, 1964	59.6	34.7	12.7
Sept. 4–9, 1964	51.4	36.2	11.2
Sept. 29–30, 1964	34.3	17.1	11.7
Oct. 13, 1964	19.4	9.3	10.4
Nov. 4, 1964	17.7	3.0	7.0
Nov. 24–30, 1964	11.3	4.9	6.3
Dec. 15–16, 1964	10.4	1.3	5.4

pastures were short and muddled, and earthworm casts abundant. Farm B, 'medium wear', although as heavily stocked as Farm A, has a lower level of soil ingestion, which agrees well with field observations that, even when pastures on this farm were short, the high proportion of stones in this soil results in a firm pavement and less muddled pasture. Farm C, 'low wear', although carrying poorer low-production pastures of native grasses and moss, has a close mat of turf, with little possibility of soil contamination. It can be seen that on this farm ingestion of soil is low.

It is intended to follow soil ingestion for a full year to obtain annual figures for soil intake. The figures gained so far suggest soil intakes of the order of 25 lb., 10 lb., and 1 lb., respectively, over the winter period on high-, medium- and low-wear farms. At peak intake ewes may be ingesting about 3 lb. soil/week on Farm A. Ingestion falls over the spring period when pastures are longer and competition for feed is reduced. Some increase in ingestion may occur over the dry summer months, but it would seem unlikely that this will approach the winter peak. It is possible that a figure approaching 50 lb./year might be obtained on high-wear farms in wet years.

It would seem, then, that there is an obvious correlation between the amount of soil ingested and the degree of wear in sheep's teeth on the three farms. While chemical agents in pasture that might contribute to wear are being investigated, at this stage ingested soil would appear to be a

Fig. 1

prime factor in wear, at least under New Zealand conditions. Although Baker *et al.*^{2,3} suggest, in a number of interesting papers, that plant phytoliths could be responsible for wear, it seems unlikely that plant phytoliths would exceed 15 g/day at the 1 kg/day dry-matter intake-level, a relatively small figure as compared with peak intakes of soil of more than 200 g/day. Further, the percentages of phytoliths in pasture samples from the three farms are not sufficiently different to explain the wear differences. This would suggest that, under New Zealand conditions, plant phytoliths are not a primary cause of wear.

After this investigation was under way it was found that another New Zealand worker, E. Suckling⁴, who was studying the effect of stocking rates on pasture composition, body-weights, wool weights, footrot, and internal parasites, had noted excessive wear in sheep at high stocking rates, which he has attributed to abrasion by soil. Co-operative studies between us now under way should enable us to establish if wear is optimal at peak soil ingestion periods.

The surprisingly high amounts of soil ingested on the high-wear farm may have other implications in the soil-plant-animal field. Ingested soil may be a significant source of microelements and of insecticides, and these aspects are also being investigated.

ENTOMOLOGY

Changes in Size of the Corpus Allatum in a Polymorphic Insect

In order to gain some insight into the part played by the endocrine system in determining form in a polymorphic insect, an investigation was undertaken of changes in volume of the corpus allatum in virginoparous alate and apterous forms of the cabbage aphid, *Brevicoryne brassicae* (L.).

Aphids of known ages were fixed in alcoholic Bouin containing 0.5 per cent trichloroacetic acid, sectioned frontally at 8 μ , and stained with iron-haematoxylin. The length and width of the corpus allatum were measured using a screw-type eyepiece micrometer and the approximate volume of the gland was calculated assuming it to be an ellipsoid having equal minor axes.

It was found that during the third and particularly the fourth nymphal instar apteriform aphids had larger corpora allata than did alatiform aphids. At the imaginal moult the corpus allatum of the apterous aphid was twice as large as that of the alate. The corpus allatum of the alate did not increase in volume between the beginning of the third instar and the imaginal moult, but by 24 h after the imaginal moult it had doubled in size. In contrast, the corpus allatum of the adult aptera decreased sharply in volume soon after the imaginal moult.

The observations on the nymphal stages support the theory that apterous characteristics may be brought about by a relatively high concentration of juvenile hormone^{1,2}.

The relative sizes of the corpora allata in adult apterous and alate aphids were particularly interesting. It has been observed that alate parents give birth almost exclusively to apterous young, while the progeny of

apterous parents may be apterous or alate³. There is also evidence which suggests that the young of alate parents are determined as apterae before birth, while the progeny of apterae may not be irreversibly determined as apterous or alate until as late as the second instar⁴. This could be explained by supposing that the form of the embryos is influenced by the hormones of the mother. An active corpus allatum in the mother would thus increase the amount of juvenile hormone passing into the embryos and direct them to the apterous pathway of development. A small or inactive corpus allatum such as occurs in apterous adult aphids would have less effect on the form of the young, and its influence could be modified postnatally by various environmental factors.

Periodic Aggregating and Take-off in Anthophorid Bees, *Anthophora acraensis* Fab.

It is well known that a number of insects refrain from work at dusk, congregate to 'sleep' (or at least to rest in a comatose state), and then resume activity as soon as it becomes bright again¹. However, little detailed work² seems to have been done on the pattern of the alighting and take-off phases of these 'sleeping' aggregations. The present observations have established both the periodicity and temporal pattern of the two phases in *Anthophora acraensis* Fab.

The observations were made between October 10 and November 14, 1964, on small groups of the species aggregating daily in the same tree in a garden at Achimota, Ghana. The number of bees in each day's group varied between 33 and 17 in October; but thereafter fell steadily until there were only 6 individuals coming to the tree on November 14. These groups consisted apparently of males only. On two separate days a single male specimen of *A. albigena* Lep. was observed among the *A. acraensis*. In analysing the results 'William's mean'³ has been used as the measure of central tendency.

The bees alighted in the evening between 1720 and 1800 h, with a peak in the period 1745–1750; spent the night on the tree, using more or less the same branches each time; and took off in the morning between 0525 and 0605 h, with a peak in the period 0535–0540 (Fig. 1—based on detailed observations made on twenty evenings and twenty mornings). This pattern was repetitive from day to day. The evening peak occurred during the first 5-min period after sunset (1745 h); whereas the morning peak occurred during the second 5-min period before sunrise (0545 h). In these circumstances, the light intensities during the two peak periods could not obviously have been the same; and records (on four evenings and five mornings) made with an 'Eel' photometer indicated that the peak and cessation of alighting occurred under greater illumination than the onset and peak of take-off (Fig. 1).

There was a general tendency for the bees to settle very close to each other on the branches, usually about half an inch apart. It was also observed frequently that attempts by oncoming bees to alight between those that had thus settled were actively repulsed, the latter raising their hind legs at the approach of the former. This behaviour towards an intruder somewhat resembles that noted by Young⁴ in the beetle, *Altica bimarginata*, aggregating to 'sleep'.

On alighting, the bees instantaneously clasped the selected branch of the tree with their mandibles and apparently spent the night like this, without using their legs for holding on. Prior to take-off they stretched their hind legs vigorously for a few minutes and became very

Fig. 1. A, Alighting; B, take-off (thick line, bees; thin line, illumination)

active. This was probably not just a simple warming-up performance, since the bees sometimes did the same thing immediately after alighting in the evening, and the wings remained folded all the time this was going on.

Early in January 1965 one or two bees were still coming to spend the night on the tree. If and when the numbers build up again, or if other similar groups of *A. acraensis* could be discovered elsewhere in the neighbourhood, it is hoped to investigate more fully the possible influence of illumination and other factors on the alighting and take-off phases and also the regularity of individual bees in these activities.

Reports published by Matthewson and Daly⁵ and Evans and Linsley⁶ confirm my observations of sleeping clusters (males only⁵), and of the clasping of branches with the mandibles.

I thank Dr. I. H. H. Yarrow for identifying the bees for me.

Relationship between the Removal of the Frontal Ganglion and Protein Starvation in *Locusta migratoria* L.

It has been shown¹ that the removal of the frontal ganglion in *Locusta migratoria* L. stopped any further growth in weight of the insect. Based on co-related changes in the endocrine system, it was suggested that failure to grow was basically a failure of protein metabolism. The possibility that cessation of growth was brought about by gross or partial starvation due to the operation interfering with the insect's ability to eat or pass food through its gut was rejected for the following reasons:

(1) The operated locusts were observed to eat frequently and to defaecate often; no obvious differences between these and normal locusts were observed in this matter.

(2) Dissections of the operated locusts revealed the presence of grass throughout the length of the gut.

(3) The operated locusts live four or five times as long as starved ones and are fully active throughout their lives. In adults, flight is not impaired in any way.

(4) The operated locusts remain at a constant weight for the rest of their lives. It is extremely improbable that just that amount of damage is done by the operation which would allow the locust to take in just that amount of food which would (a) make good the loss of weight due to post-operative treatment, (b) precisely make good the daily energy expenditure of the animal.

(5) The oxygen consumption of operated locusts was not significantly different from normal locusts, while that of starved animals is always significantly lower.

(6) The effects of starvation could be reversed by simply giving the locusts food, but no way of correcting the results of the removal of the frontal ganglion was found.

Since the publication of this work, the possibility has been raised a number of times that starvation, that is the failure of the animal to take into its gut sufficient food for growth, was responsible for the observed results. This theory has been put forward sufficiently often to warrant re-iteration of the original reasons together with

Fig. 1. The percentage change in weight of fourth instar *Locusta migratoria* from which the frontal ganglion has been removed within 24 h of ecdysis (hour 0) and daily injections commenced at 80 h. ●—●, Locusts which were injected with corpora cardiaca extract; ×—×, locusts which received control injections. Each curve represents the responses of one individual

a brief statement of the extra facts (taken from our continuing programme of research into the physiological effects of the removal of the frontal ganglion):

(a) Active proteinases are present in the gut of operated locusts and in operated controls. In the operated controls the amount present increases as the animal grows; in the operated locusts the amount remains the same as it was at the time of the operation.

(b) Studies on ^{14}C -glycine injected into the haemocoel (thus by-passing any barrier the gut may present) of operated locusts and operated controls show that it is incorporated into the tissues of the former to a much lesser extent than in the latter.

(c) Daily injections of an extract of corpora cardiaca taken from normal locusts caused near normal growth in operated locusts (Fig. 1). Control injections are without effect.

From the evidence given here the following relationship is deduced between forcibly starved locusts and those from which the frontal ganglion has been removed but are in the presence of abundant food and water.

The effect of the operation is to stop, or reduce to a very low level, protein synthesis in the insect's body. This effect can also be achieved by forcibly starving locusts, either completely by withholding all food, or specifically by withholding all protein. The gross effect of these two procedures is similar, but they are fundamentally different for the following reason. In operated locusts it is the machinery of protein synthesis that has been interfered with, while in starved locusts it is the fuel which is being withheld.

Further work has shown that the removal of the frontal ganglion affects protein metabolism by way of the action of the corpora cardiaca hormones and the synthesis of mRNA in the tissue cells. We are affecting, therefore, the growth of the locust at a far more fundamental level than is achieved by starvation and, by the proper exploitation of the effects of the removal of the frontal ganglion, learning much about the control of growth and metabolism in the insect.

MICROBIOLOGY

Isolation of Bacteria able to metabolize Fluoroacetate or Fluoroacetamide

FLUOROACETATE or fluoroacetamide, after conversion to fluorocitrate, inhibit aconitase¹ and therefore block the tricarboxylic acid cycle; consequently these chemicals are toxic to animals and are used as pesticides. There have been at least two occasions when accidental contamination of soil and water by fluoroacetamide has occurred². This communication reports the isolation of bacteria able to use these compounds for growth.

Agar plates containing mineral salts medium³ with 25 mM fluoroacetate as carbon source and 25 mM ammonium chloride as nitrogen source, pH 7.2, were inoculated with aqueous extract from garden soil or water from Dartford Creek (Kent) and incubated at 30°. Those inoculated with water produced small yellowish colonies after incubating for about fourteen days; the others were still negative after three weeks. A single colony was sub-cultured on fresh fluoroacetate agar; satisfactory growth was obtained in five days and the colony isolation procedure was repeated. The bacteria were short, non-motile, Gram-negative rods and occurred singly, in pairs or, very rarely, in short chains. Growth on fluoroacetate agar plates was slow; colonies

were homogeneous, yellowish in colour, small, flat and circular. On nutrient agar, growth was more rapid and colonies were larger than on fluoroacetate but otherwise very similar in appearance. The bacteria grew more slowly at 37° than at 30° on both nutrient agar and fluoroacetate. Fluoroacetamide, glucose, fructose, mannose, lactose, mannitol and glycerol could serve as carbon sources for growth; citrate was not used. A culture has been deposited with the National Collection of Industrial Bacteria and assigned the number 9562.

Fig. 1 illustrates growth of the isolate in an aerated liquid medium containing fluoroacetamide; an uninoculated flask served as control. The pH values and optical densities were measured at intervals and, after removal of bacteria by centrifugation, inorganic fluoride and fluoroacetamide were determined (Snell and Snell^{4,5}). In the control flask the level of fluoroacetamide remained constant. A blank reading equivalent to 2 $\mu\text{moles/ml}$. of fluoride was obtained at the start of the experiment and did not change. In the inoculated flask the level of fluoroacetamide slowly decreased until, after 9 days, none could be detected. There was a corresponding increase in the level of fluoride. Growth was linear, not exponential, throughout most of the growth curve. The pH of the control remained constant whereas that of the inoculated culture dropped to 6.8. In corresponding experiments using fluoroacetate medium, approximately 40 mM fluoride was present in the growth medium supernatant after 6 days' incubation at 30°.

For experiments with resting cells, bacteria were grown under forced aeration in 250 ml. amounts of mineral salt medium containing 40 mM succinate, acetate, fluoroacetate or fluoroacetamide as carbon source. Fluoroacetamide also served as nitrogen source and was sterilized by filtration; other media had 40 mM ammonium chloride as nitrogen source and were sterilized by autoclaving. Succinate or acetate medium supported yields of about 0.7 mg dry weight of bacteria/ml. in 24–36 h, whereas comparable growth in fluoroacetate or fluoroacetamide took 5–10 days. Cells were collected by centrifugation, washed once in 0.05 M phosphate, pH 7.4, and re-suspended in more of the same buffer.

Cells grown with acetate oxidized acetate or succinate immediately; those grown with succinate oxidized succinate at once but showed a slight lag with acetate. Neither type metabolized fluoro-compounds during 90 min. Fig. 2 illustrates that those grown on fluoroacetate oxidized this substrate or acetate but not fluoroacetamide. Those grown on fluoroacetamide oxidized this compound, fluoroacetate or acetate.

Thus these bacteria grow with fluoroacetate or fluoroacetamide adaptively but very slowly; the non-exponen-

Fig. 2. *a*, Oxidation of \circ fluoroacetate; \bullet , fluoroacetamide and \square , acetate by resting cells grown with 40 mM fluoroacetate; \circ signifies control. Each Warburg flask contained the equivalent of 8.5 mg dry wt. of cells; 100 μ moles potassium phosphate buffer, pH 7.4, temperature 30°. At the point marked \downarrow 10 μ moles of substrate were added. *b*, Oxidation of substrates by the equivalent of 8 mg dry wt. of cells grown with 40 mM fluoroacetamide. Conditions otherwise as for *a*.

tial character of growth suggests that product inhibition occurs. The amide is probably converted to the acid by an adaptive amidase. Since permease formation is unlikely to provide a complete explanation of the adaptive nature of fluoro-compound metabolism, further investigations of this organism would be of particular interest because it could contain either an unusual aconitase or an enzyme specific to fluorine-carbon linkages. Suitably adapted strains might be of value for the decontamination of soils and water.

CYTOLOGY

Functional Similarities between the Cytoplasmic Organelles of Melanocytes and the Mitochondria of Hepatocytes

In an earlier communication¹, it was reported that the cytoplasm of melanocytes, located in the liver of the amphibian *Amphiuma*, is packed with large organelles containing melanin granules in varying numbers. These melanocytes have few mitochondria and no visible ribosomes, in contrast to the hepatocytes which present the familiar organelles in large numbers. The sharp structural differences between the respective liver cells evoked our interest in comparing the functions of the organelles which abound in each. The insight to be gained from such investigations seemed to transcend the particular melanocytes under discussion: normal cells with similar structures are being seen in other organs²⁻⁴ and in other vertebrates^{5,6}, while abnormal metabolism of melanins is being encountered in human diseases ranging from neoplasia⁷ to extrapyramidal disorders of the brain^{8,9}.

For reasons which will become evident, the investigations recorded here were restricted to comparisons between mitochondria and melanin-containing organelles. Both had to be isolated from their respective cells in useful

yields and without intercontamination. Centrifugal fractionations of 10 per cent homogenates in 0.25 M sucrose showed that the technique of Schneider and Hogeboom¹⁰ was applicable to the collection of pure *Amphiuma* liver mitochondria. This technique had to be modified for the isolation of the melanin bodies: although these organelles were larger and heavier than the mitochondria, their separation in pure form necessitated the use of a sharp gradient. Since these organelles disintegrated in 30 per cent sucrose (0.88 M), 30 per cent dextran (0.002 M) was used successfully instead. These bodies also disintegrated at low pH and with routine homogenization. Hence the suspending media contained 0.02 M phosphate buffer, pH 7.4, and instead of a Potter-Elvehjem homogenizer a Latapie mincer was used.

The following technique is used at present: the mince is suspended in 10 volumes of 0.25 M sucrose at 4° C. The suspension is filtered through paper (Schleicher and Schull, No. 588) to remove tissue fragments, red cells and isolated nuclei. The filtrate is spun at 1,000g for 15 min. To obtain melanin-containing organelles the sediment is re-suspended in 2 ml. of 0.25 M sucrose; this suspension is layered over 15 ml. of 30 per cent neutralized dextran and the system is centrifuged for 35 min at 1,000g. The ensuing pellet consists of melanin-containing organelles and few free melanin granules but no visible mitochondria. The latter are gathered from the supernatant of the initial filtrate, by centrifuging at 5,000g. These are comparable to the mitochondria derived from liver homogenates according to the unmodified method of Schneider and Hogeboom¹⁰. The purity of both fractions was ascertained by light and electron microscopy (Fig. 1). Isolated melanocytes, obtained by incubation of liver slices with collagenase, yielded inferior preparations.

Metal-transport into each of these organelles was measured by assaying their uptake of carrier-free ⁵⁴MnCl₂ which was injected intraperitoneally. This isotope was selected because it accumulates preferentially in mammalian liver mitochondria both *in vivo*¹¹ and *in vitro*¹². Twenty-four hours after injection of 50 μ c., the whole liver contained 1.99×10^5 c.p.m./mmole nitrogen. By comparison, the washed mitochondria contained 2.22×10^5 c.p.m./mmole nitrogen, and the washed melanin organelles contained 2.02×10^5 c.p.m./mmole nitrogen. Repetition of this experiment yielded similar results.

Fig. 1. Electronmicrograph of osmium-fixed, uranyl-acetate-stained cytoplasmic organelles of melanocytes isolated from *Amphiuma* liver by 30 per cent dextran gradient centrifugation. Some free melanin granules are also present. ($\times c. 5,904$)

Fig. 2. Comparison of the loss of both the radioisotope ^{54}Mn and the natural isotope ^{55}Mn from the melanin granules of the *Amphiuma* liver. The melanin granules were isolated and washed by differential centrifugation in neutral distilled water. The amounts of ^{54}Mn and ^{55}Mn in the whole liver, prior to the isolation of the melanin granules, are shown at each vertical margin of the graph.

On a previous occasion, melanins from other sources were observed to contain high concentrations of natural, non-radioactive manganese¹³. Hence it was of interest to analyse the melanin granules located within the matrix of the organelles under discussion. Such analyses would show whether manganese crosses the membranes of the melanin granules: or only those of the melanocytes and of the organelles which contain these granules.

The melanin granules were isolated according to Claude¹⁴ after one initial wash with triple-distilled demineralized water. The concentrations of both the radioisotope ^{54}Mn and the natural isotope ^{55}Mn were determined as follows: The radioactive one was determined first, the natural one was rendered radioactive by neutron bombardment¹⁵ and the ensuing ^{56}Mn was quantified after subtraction of the long-lived radioactivity of ^{54}Mn . The results are shown in Fig. 2. The initial high degree of accumulation shown on the figure constitutes an underestimate of the native state, since subsequent washings decreased the concentration of both isotopes in these granules.

These results showed that the melanin-containing organelles concentrate manganese in a manner similar to mammalian mitochondria. They indicated the desirability of further comparisons between the novel organelles and the mitochondria. Among the enzymes known to be mitochondrial ones in the mammal, the following were selected: (1) succinic oxidase¹⁶ because of its importance in energy metabolism¹⁷; (2) monoamine oxidase¹⁸ because of the production of melanins which accompanies its reaction *in vitro*^{19,20}. These considerations prevailed in spite of the known lability of these enzymes, particularly in the amphibian²¹.

The lability of these enzymes reflected itself in the fact that the sum of fractions obtained according to Schneider and Hogeboom¹⁰ contained less activity than did the initial homogenate. The losses did not exceed 30 per cent and were not reflected in the recoveries of either ^{54}Mn or of nitrogen. Still, it was necessary to ascertain whether

the particular fractions of interest to us were not primarily affected. These fractions were therefore tested before and after incubation at 4°C overnight. No losses of either enzymatic activity were found in the isolated mitochondria. The whole liver homogenate lost only about 15 per cent of its succinic oxidase but none of its monoamine oxidase activity. In contrast, the melanin-containing organelles lost about 45 per cent of their succinic oxidase and only 10 per cent of their monoamine oxidase activity. Hence it was evident that the enzymatic activities recovered with the melanin-containing bodies would constitute underestimates of the native state.

The relative specific activities of these two enzymes are shown in Table 1 as the mean and range for each. It is evident that both enzymes were localized to about the same degree in the melanin-containing bodies and the mitochondria. The melanin granules isolated from the organelles which contain them had contributed significant amounts of nitrogen to these computations, but they contained no measurable enzymatic activity.

Table 1. SUCCINIC OXIDASE AND MONOAMINE OXIDASE IN *Amphiuma* LIVER FRACTIONS

	Succinic oxidase ($\mu\text{l. O}_2/\text{h/mM N}$)	Monoamine oxidase ($\mu\text{M NH}_3/\text{h/mM N}$)
Homogenate (5)	762 (512-908)	28 (22-34)
Mitochondria (8)	954 (232-1,703)	57 (30-120)
Melanin bodies (8)	758 (305-1,297)	38 (12-83)

The sum of this evidence indicates that some mitochondrial functions are localized also in the recently described organelles of the melanocytes in *Amphiuma* liver¹. This is indeed in agreement with the conclusions of du Buy *et al.*²² in spite of the fact that we have investigated large, complex organelles from a normal tissue, whereas their material contained melanin granules and small melanosomes from mammalian tumours. It should be recalled that the melanocytes examined here contained no visible ribosomes or lysosomes. Hence the melanin-containing organelles are worth comparing with ribosomes and with lysosomes in a manner similar to that reported here for mitochondria.

We thank Dr. Horton A. Johnson for his preparation and interpretation of the electronmicrographs.

VIROLOGY

Growth and Cytopathogenicity of *H*-viruses in Human and Simian Cell Cultures

THE *H*-viruses are a new group of small agents, 180–250 Å in diameter, distinguished by their ability to produce a 'mongoloid-type' deformity in new-born hamsters^{1,2} and, in the case of *H*-1, to cross the placenta and cause malformation of the hamster embryo^{3–5}. These viruses have been isolated from two host sources, man and rat. Two members of the group, *H*-1 and *H*-3, which differ from one another serologically, were first isolated from human tumours transplanted in conditioned animals; afterwards they, as well as *HT* and *HB*, were obtained directly from human embryos, placentas, and neoplasms⁶. Recently it was demonstrated that two human subjects injected with *H*-1 virus developed haemagglutination-inhibiting (HA-I) and neutralizing antibodies to *H*-1 (ref. 7). This indication that man is susceptible to infection by *H*-1 virus is supported by the observation that HA-I and neutralizing antibodies to *H*-1 virus have been found in the sera of several cancer patients, laboratory personnel, and pregnant women^{6,8}. It has also been learned that rhesus monkeys are susceptible to infection with *H*-1 (ref. 9).

Other members of the *H*-group, the Kilham virus, *RV* (ref. 10), and the related virus *X*-14 (ref. 11), both of which are serologically similar to *H*-3 though they have different types of haemagglutination patterns with red blood cells from various animals, have been isolated from rat tumours. So far only rat embryo cells, and occasionally hamster embryo cells, have been used to grow *H*-1 or *RV* (refs. 11–15). This communication reports that *H*-1 and *H*-3 can proliferate and be passaged in a number of human and simian cell culture lines.

The cells tested for growth of the *H*-viruses are listed in Table 1. The human continuous cell lines of HeLa (Gey), HeLa S-3 and FL amnion were obtained from Difco Laboratories, Detroit, Michigan; Chang liver, Chang conjunctiva and Henle intestine from Baltimore Biological Laboratories, Baltimore, Maryland; and Hep-2 from Flow Laboratories, Rockville, Maryland. Primary cultures of human amnion were prepared in the laboratory from fresh placentas by the method of Wilt *et al.*¹⁶. The permanent simian cultures of rhesus kidney (*LLC-MK* 2), Salk heart and chimpanzee liver (Douglas *CL* I) came from Flow Laboratories. Other cells tested were the permanent hamster kidney culture, *HaK*, from Flow Laboratories, and secondary hamster embryo cultures

derived from trypsinized primary cultures of minced hamster embryos, approximately 14 days of age. Cell sheets were prepared by growing trypsinized cells in 30 ml. Falcon tissue culture flasks containing 5.0 ml. of Eagle's minimum essential medium (MEM) with 10 per cent calf serum. When an almost confluent layer of cells formed, the test cultures were washed twice with tris-buffered saline (TBS) (ref. 17) and infected with 1.0 ml. of virus prepared from infected new-born hamster livers¹⁸ and diluted with TBS to contain 10–20 haemagglutinin (HA) units/ml. Parallel titrations of *H*-1 and *H*-3 strains were done. After incubation for 2 h at 37° C, the control and infected cultures were washed twice with TBS and covered with 5.0 ml. of MEM containing 2 per cent foetal calf serum. The cultures were examined daily or at suitable intervals for haemagglutinin production and for the development of cytopathic changes (CPE). For HA titrations guinea-pig red cells were used¹⁸. End-points were read as that dilution of virus which completely agglutinated all the red cells.

Growth of *H*-1 and *H*-3 was obtained in all the permanent human cell lines tested (Table 1). Although both viruses appeared to multiply to approximately the same extent, producing maximal HA titres at about the same time, the cells differed in their response to the two viruses. The CPE induced by *H*-1 appeared earlier, concomitant with virus multiplication, and progressed considerably more rapidly than that induced by *H*-3. Early CPE consisted of rounding of cells and granularity, followed by a disruption of the cell sheet, and finally detachment of the necrotic and shrunken cells. This CPE was very similar to that found in infected rat embryo cultures by Moore¹². The difference in the timing and progression of cellular pathogenicity induced by *H*-1 and *H*-3 in human cells was also observed in the permanent simian cell lines of Salk monkey heart and Douglas chimpanzee liver, the permanent hamster kidney line, *HaK*, and the secondary hamster embryo cultures. Only minimal CPE by *H*-3 was seen at the time when maximal or nearly maximal haemagglutinin production occurred. However, although the CPE induced by *H*-3 was delayed, a slow progression to fairly complete CPE usually occurred. It is noteworthy that it took considerably longer for maximal HA production and CPE to occur in the hamster cells than in the human and simian cultures. Whether this finding represents a genuine difference in cell susceptibility or could be attributed to other factors, such as variations in cell concentration, is unknown.

Several successful passages of *H*-1 and *H*-3 were carried out in all the cell lines tested. After three to five passages

Table 1. SUSCEPTIBILITY OF CELLS OF DIFFERENT ORIGIN TO *H*-VIRUSES

Source	Cell	Maximal haemagglutinin (HA) production*		Days after inoculation maximal HA obtained		CPE at time maximal HA obtained†		
		H-1 virus	H-3 virus	H-1 virus	H-3 virus	H-1 virus	H-3 virus	
Human	Permanent	HeLa (Gey)	4	not done	5	not done	4	not done
		HeLa S-3	3	2	4	3	3	1
		Liver (Chang)	4	4	4	3	4	1
		Conjunctiva (Chang)	3	3	5	3	3	1
		Intestine (Henle)	3	3	4	4	4	1
		HEp-2	3	not done	6	not done	3	not done
		FL amnion	3	4	4	4	3	1
	Primary	Embryo kidney	0	0	21 days observation	—	—	—
		Amnion	0	0	23 days observation	—	—	—
	Simian	Permanent	Rhesus kidney, LLC-MK 2 (Hull)	0	0	23 days observation	—	—
Monkey heart (Salk)			4	4	5	8	3	2
Chimpanzee liver (Douglas)			4	4	4	6	4	1
Other	Permanent	HaK (kidney, Syrian hamster) (Spence)	4	3	12	15	3	1
		Hamster embryo	3	3	9	7	3	1

* Haemagglutinin production was assayed by haemagglutination of guinea-pig red cells and reported in haemagglutination units as the reciprocal of the highest dilution that completely agglutinated all the red cells as follows: 1, 10–20 units; 2, 40–160 units; 3, 320–640 units; 4, 1,280+ units.

† Cytopathic changes (CPE) were graded as follows: 1, rounding and granularity of scattered cells; 2, beginning of disruption of cell sheet; 3, extensive cellular granularity and disruption of sheet; 4, considerable detachment of degenerated cells.

of H-3, extensive CPE occurred when haemagglutinin production became maximal. H-1 is at present in its sixth passage in Chang liver and Salk monkey heart and so far has retained its full virulence for new-born hamsters. The finding that H-1 and H-3 failed to produce HA or CPE in the primary human embryonic kidney or amnion tissue cultures is of interest and is being investigated.

Stimulation of Sendai Virus Multiplication by Puromycin and Actinomycin D

THE rate of virus multiplication may ultimately be limited by the number of unprogrammed ribosomes available to viral nucleic acid. There is presumably only a finite probability in unit time that an infecting viral nucleic acid molecule can successfully compete with a vast excess of cellular messenger RNA molecules for an unoccupied ribosome. Even after attachment has been achieved, the subsequent rate of synthesis of viral constituents may be expected to depend on the availability of free ribosomes. This hypothesis was tested experimentally in cells pre-treated with two antibiotics, puromycin and actinomycin D, each capable of increasing the number of unprogrammed ribosomes.

Actinomycin D inhibits the synthesis of messenger RNA by binding to DNA and interfering by steric hindrance with the function of DNA-dependent RNA polymerase^{1,2}. This leads to the gradual disappearance of polyribosomes with a consequent increase in the number of unprogrammed ribosomes³ as existing messenger RNA is slowly destroyed during the ensuing few hours^{1,3,4}. Sendai is one of several RNA viruses capable of normal multiplication in the presence of actinomycin D^{1,5}. It commends itself for the proposed experiment because, by analogy with other myxoviruses^{6,7}, it probably does not bring about the early inhibition of host cell protein or messenger RNA synthesis so evident, for example, with mengovirus⁸ and poliovirus⁴.

The parameters of Sendai virus multiplication were examined in suspended allantois-on-shell⁹. Dilutions of virus were added to pieces of allantois-on-shell (AOS) cut from a single egg and suspended in a simple maintenance medium in a plastic tray. The tray was shaken at 36.5° for 30 min, then 100 units of receptor-destroying enzyme (RDE) added to remove residual inoculum and to restrict virus multiplication to a single cycle. After rinsing, the tissues were transferred to a fresh tray every 2 h and the

Fig. 1. 'Delay'¹⁰ in the multiplication of Sendai virus. AOS was inoculated with Sendai at m.o.i. of 100 (open circles), 30 (closed circles), 10 (open squares), 3 (closed squares), 1 (open triangles) or 0.3 (closed triangles). The graph shows the amount of haemagglutinin newly produced in each 2-h interval.

remaining supernatant fluids titrated for their content of haemagglutinin (Fig. 1).

At high multiplicity of infection (m.o.i.) virus begins to appear after an eclipse period of 6½–7 h and the maximum rate of virus production (given by the peak of the differential curve) is seen during the tenth or eleventh hour post-infection (p.i.). At low m.o.i., on the other hand, the eclipse period is longer and the rate of virus production is still increasing at 16 h. This clearly establishes the occurrence of multiplicity-dependent 'delay'¹⁰ in the multiplication of Sendai virus.

Actinomycin D (0.03, 0.1, 0.3, 1, 3, 10 µg/ml. or nil) was added to AOS 2 h before Sendai virus at various m.o.i., and cumulative yields of haemagglutinin were titrated. Regardless of m.o.i. and at concentrations of actinomycin of 0.3 µg/ml. to 10 µg/ml. inclusive, the antibiotic markedly increased the rate of virus production. Fig. 2 shows the results of a typical experiment using actinomycin at 2 µg/ml. There is good reason to suppose that the increase would be even greater if the cells could be maintained in actinomycin for a longer period before infection to allow more adequate time for decay of existing messenger RNA.

Puromycin inhibits protein synthesis by removing the developing peptide chains from ribosomes¹¹. As a result

Fig. 2. Stimulation of Sendai virus multiplication by actinomycin D. AOS was inoculated with actinomycin D, then 2 h later with various m.o.i. of Sendai virus. Cumulative yields of haemagglutinin were titrated at 2-h intervals. Closed symbols, controls; open symbols, actinomycin-treated. Circles, m.o.i. 60; squares, m.o.i. 20; triangles, m.o.i. 6; inverted triangles, m.o.i. 2; diamonds, m.o.i. 0.6.

messenger RNA is released and polyribosomes are disaggregated¹². AOS was treated with puromycin (1, 3, 10, 30, 100, 300 µg/ml. or nil) for 2 h before infection with Sendai virus (m.o.i. = 1). The drug was removed and the membranes were rinsed immediately before infection, then again on removal of RDE and residual inoculum 30 min later. Cumulative yields of virus were titrated as before. To serve as controls, comparable membranes were treated with *p*-fluorophenylalanine (600 µg/ml.), which inhibits protein synthesis just as effectively but in a completely different way¹³. At a concentration of 300 µg/ml. puromycin actually retarded multiplication because it could not be removed completely by rinsing. However at concentrations of 30 µg/ml. and 100 µg/ml., puromycin consistently stimulated the rate of virus production. Results from two such experiments are given in Table 1.

Table 1. EFFECT OF PUROMYCIN, ACTINOMYCIN D AND FPA ON THE MULTIPLICATION OF SENDAI VIRUS

Treatment	Cumulative yield of virus (haemagglutinin)				
	9 h	11 h	13 h	15 h	17 h
Experiment 1 (m.o.i. = 0.5)					
Control	—	—	3.0	6.2	9.4
FPA (600 µg/ml.)	—	—	2.3	6.5	9.8
Puromycin (30 µg/ml.)	—	1.2	6.0	12.4	17.6
Actinomycin D (2 µg/ml.)	—	3.8	15.0	29.4	37.4
Actinomycin D + puromycin	—	3.4	13.0	25.0	31.8
Experiment 2 (m.o.i. = 1)					
Control	—	2.8	6.8	10.0	13.2
FPA (600 µg/ml.)	—	1.8	5.8	9.0	12.7
Puromycin (30 µg/ml.)	—	3.4	9.4	15.0	18.6
Actinomycin D (2 µg/ml.)	2.4	15.2	29.6	43.2	53.6
Actinomycin D + puromycin	0.8	7.2	16.0	23.6	30.0

Doubtless the degree of stimulation would have been greater had it been possible to remove the puromycin more effectively. That residual traces of the drug actually inhibit virus multiplication can be seen from the fact that pretreatment with puromycin plus actinomycin D gives substantially less stimulation than actinomycin alone. Nevertheless pretreatment with puromycin alone does enhance the rate of virus production. The fact that *p*-fluorophenylalanine (FPA) is ineffective shows that the stimulating activity of puromycin is attributable not to the inhibition of protein synthesis *per se*, but to some more specific action of the drug. Had it proved experimentally practicable to use larger concentrations of puromycin or to leave it in until immediately before viral protein synthesis began, the degree of stimulation by puromycin may well have been comparable with that obtained with actinomycin.

A recent report by Heller¹⁴ indicates that actinomycin can increase yields of Chikungunya virus by inhibiting the synthesis of interferon and so preventing the late decline in virus production that otherwise occurs following the first cycle of multiplication in cell cultures inoculated with virus at low m.o.i. It seems unlikely that our own results have anything to do with interferon, because all experiments were confined to a single cycle of infection, and stimulation of the rate of virus production is apparent from the moment new virus becomes detectable at the end of the eclipse period. Bukrinskaya and Zhdanov⁵ have recently reported a shortening of the Sendai eclipse period by actinomycin D without any increase in viral multiplication rate or total yield. By contrast, Fig. 1 in a paper by Wheelock¹⁵ reveals a slight (25–30 per cent) stimulation of final yield of NDV in the presence of actinomycin without any increase in multiplication rate or shortening of the eclipse period.

Our experiments demonstrate that both actinomycin D and puromycin stimulate the rate of virus production. As a result the yield is also increased (the relative increase being greater the later the yield is titrated) and the eclipse period appears to be shortened because the yield reaches the lower limit of detection earlier. Both antibiotics may act by making available to viral RNA greater numbers of unprogrammed ribosomes.

This work was supported by a grant from the National Health and Medical Research Council of Australia, and one of us (I. M. C.) was supported by the Commonwealth

Serum Laboratories Commission. The actinomycin D was a gift from Merck, Sharpe and Dohme Research Laboratories, New Jersey.

GENETICS

A Lactate Dehydrogenase Variant in the Mouse

A GENETICALLY determined lactate dehydrogenase (LDH) variant has been demonstrated in the mouse, using starch-gel electrophoresis. After electrophoresis, the sliced surface of the gel is incubated with lactate substrate.

Table 1. RESULTS OF TEST-CROSSES

Cross	C57BL pattern	F ₁ pattern	CBA pattern	Total
C57BL♂ × F ₁ ♀	22	19	0	41
F ₁ ♂ × C57BL♀	15	11	0	26
	37	30	0	67
CBA♂ × F ₁ ♀	0	9	5	14
F ₁ ♂ × CBA♀	0	9	6	15
	0	18	11	29

The work recorded here was carried out on two inbred mouse strains, CBA and C57BL. All haemolysates contain the LDH isozyme band which moves most slowly towards the anode in tissue homogenates. Adult CBA mice have a second, faster-moving band, which is roughly equal in intensity to the slow band. This band is either absent or very faint in adult C57BL mice. A band of intermediate intensity is present in hybrids from both reciprocal crosses (Fig. 1). The variable band is not present in new-born CBA mice and appears to increase with age of the mouse (Fig. 2). Animals were screened only after they were at least 90 days old, by which time the pattern had become stable. Controls of the same age were always used. Test-cross data indicate that the variant is determined by a single gene (Table 1). Further work on red cells and on

Fig. 1. Starch-gel electrophoresis of LDH in mouse haemolysates

Fig. 2. Starch-gel electrophoresis of LDH in CBA mice of various ages

tissue homogenates is in progress to determine more about the nature of the variant LDH.

PSYCHOLOGY

A General Theory for the Evolution of Intelligent Behaviour

THE problem of the evolution of intelligent behaviour has recently achieved publicity¹ in relation to work on the learning abilities of various vertebrates². Over the past three years I have developed a general theory of the evolution of intelligence from, and within the framework of, an instinct system of Lorenz-Tinbergen type³. This theory is of wider scope than any which could be advanced on the basis of the present theories of learning; it can, it is felt, accommodate most of the 'learning theory' views; and it appears to provide a context for the understanding of a considerable variety of other phenomena. An extended account and discussion of this general theory of the evolution of intelligence is being offered for publication elsewhere—but a very brief preliminary account appears desirable, to stimulate interdisciplinary appraisal and discussion.

If a generalized and non-committal view of intelligent behaviour be adopted, namely, that its salient characteristic is adaptive variability, the evolutionary problem can be stated in terms of the generation and selection of this characteristic from out of the relative fixity and rigidity of a system of instinctive behaviour. Detailed analysis of what is involved brings to light three features or 'factors' which must be represented in the finally-produced 'intelligence'. There must develop: (1) a capacity not to respond (or to delay the response) to the 'releasers'⁴ of responses which were previously normal, so as to allow the substitution of new kinds of response; (2) a dynamic 'memory store', 'knowledge' of the environ-

ment in relation to the individual animal, on the basis of which new responses can be elaborated; (3) an ability to abstract and generalize, to perceive similarities and differences, so that in the light of the past experience of the individual (2), the new variants of behaviour can be made adaptive as quickly as possible.

These three features correspond remarkably with three factors isolated by Halstead⁵ within 'biological intelligence'. The foregoing three features mentioned correspond to Halstead's *P*, *C*, and *A* factors respectively. Halstead's fourth, the *D* factor, is one which measures the efficiency of the individual's sensorimotor intercourse with the environment—and this must be under positive selection alike in 'intelligent' and in 'instinctive' animals. Halstead's approach was through the analysis of the behaviour-impairment of brain-injured humans; and the agreement between conclusions arrived at by very different routes is felt to constitute strong support for the view of intelligence which has emerged.

The Russells⁶ have shown the relevance of Halstead's 'biological intelligence' to the differentiation between normal and pathological behaviour in humans. The concept of 4-factor biological intelligence developed severally by Halstead and myself is also illuminating with regard to present researches into personality differences among scientists⁷, and into 'creativity' in humans⁸; and it provides a theoretical framework for the interpretation of some neurological experiments⁹ and various other phenomena. Exploratory activity, and play, assume an enhanced significance; further discussions will be offered for publication elsewhere.

I am greatly indebted for encouragement and criticism in the development of this work to Dr. N. Tinbergen, and to my friends and colleagues, G. F. K. Naylor, M. C. Bleakly, M. J. Thorne, and D. Judge.

Effect of Foster-mothers' Strain and Pre-natal Experience on Adult Behaviour in Rats

THE examination of the effects of the experiences of one generation on the behaviour of their offspring is of intrinsic interest. It is also of importance in relation to experiments in both psychogenetics and the study of the effects of pre-natal environments. Experiments with rodents have shown that both the strain and the early experiences of foster-parents can affect the later behaviour of the offspring they rear. Thus Ressler¹ showed that the strain of the foster-parents of mice can affect the later exploratory behaviour of the fostered offspring. Such effects may be mediated by differences in parental behaviour towards the pups², and, since the behaviour of parent animals can be affected by their own experiences, the behaviour of an organism can thus be affected by the previous experience of the parents which rear it.

Denenberg and Whimbey³ have shown that the weaning weights of rats and later their emotional defaecation scores in the open field were significantly influenced by the experiences their mothers had had as infants, and Ressler⁴ that the visual exploration scores of offspring of mice, which had been reared by either one of two strains of foster-parents or by their biological parents,

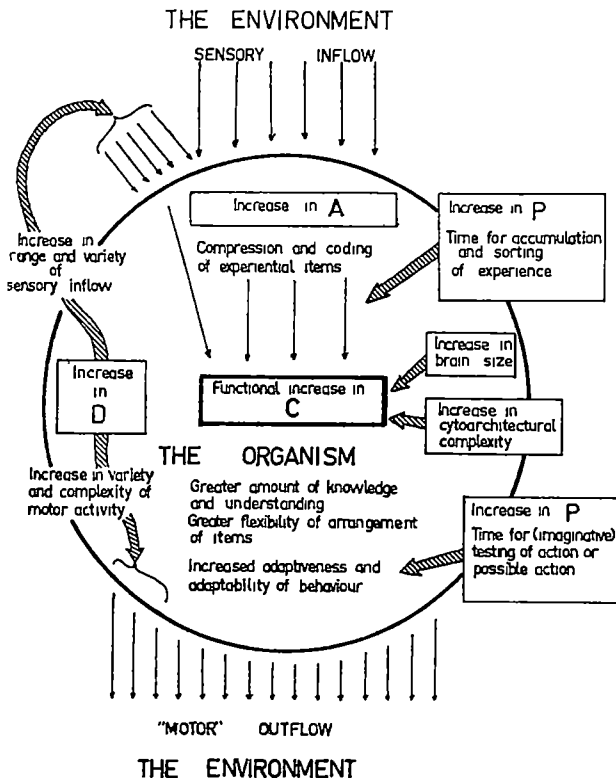

Fig. 1. Four-factor biological intelligence in evolution

were affected by the strain of their foster-grandparents, as well as by the fostering procedure *per se* carried out on their parents.

The experiment recorded here was carried out to explore further these aspects of parent-offspring interaction by using subjects from genetically uniform mothers, with the offspring reared to weaning by foster-mothers which differed in both experience and heredity. It also differs from previous experiments both in using two intensities of the experimental treatment administered to the foster-mothers and in applying them to the mothers in their maturity rather than in their infancy. In this way, the results may have some bearing on the adequacy of using biological mothers as rearing mothers in experiments on pre-natal stress.

Twelve litters of rats were fostered shortly after birth to a foster-mother of one of two strains, the Maudsley reactive (MR) or non-reactive (MNR) strains, selectively bred for 23 generations for high and low emotional defaecation respectively^{5,6}. Each foster-mother had previously received one of the following three treatments:

(1) Pre-mating avoidance training plus gestational stress: 14 days training to avoid shock of 0.3 m.amp (UCS) on presentation of a CS (illumination change) in a shuttle box, then mating, then 18 days of further trials in the shuttle box with no shock presented and the avoidance response physically blocked on 16 of the 24 daily trials. (2) Pre-mating avoidance training only: 14 days shuttle box training, mating, no further disturbance. (3) Controls: no disturbance other than mating.

The biological mothers of the subjects used were 12 primiparous, experimentally naïve females of the MNR strain, also at S_{23} ; the 12 litters were thus genetically homogeneous. Offspring were weaned at 21 days, ear-punched for identification at 50 days, and otherwise left undisturbed until tested at approximately 100 days of age.

At this stage 48 offspring (two males and two females randomly chosen from each of the 12 litters), equally divided among the two strains and the three pre-natal treatments of their foster-mothers, were tested in the standardized open-field test of emotionality (four daily 2-min trials)⁵ and on an avoidance conditioning task (one 50-trial session; UCS, shock of 0.25 m.amp; CS, a buzzer). Half were tested in the order stated and half in the reverse order.

In the analyses of variance applied to the resulting data, main effects and interactions based on between-litter comparisons were tested against between-litter error; if between-litter error was not significantly different from within-litter error, the two were pooled to provide an overall error variance.

There was a significant difference in the conditioning scores of subjects reared by mothers which had been stressed pre-natally. Both number of avoidances ($F = 5.63$, $P < 0.01$ with 2, 41, d.f.) and mean latency of response ($F = 5.74$, $P < 0.01$ with 2, 41 d.f.) differed significantly as a result of maternal experiences. The relevant means and standard deviations are shown in Table 1. Scheffe's test for multiple comparisons between means indicates that on both scores the group which had experienced pre-mating stress only is significantly inferior

Table 1 MEANS AND STANDARD DEVIATION FOR NUMBER OF AVOIDANCE SCORES AND AVOIDANCE LATENCIES IN CONDITIONING OF FOSTER-LITTERS REARED BY MOTHERS OF DIFFERENT EXPERIENCE

Experience of foster-mother	Avoidances (out of 50) (mean \pm S.D.)	Latencies (sec) (mean \pm S.D.)
Pre-mating plus gestational stress	32.7 \pm 12.9	4.4 \pm 2.01
Pre-mating stress only	29.4 \pm 11.9	5.1 \pm 1.91
Controls	38.1 \pm 11.5	3.5 \pm 1.63

Table 2. MEANS AND STANDARD DEVIATIONS FOR NUMBER OF AVOIDANCE SCORES AND AVOIDANCE LATENCIES IN CONDITIONING OF THE TWO SEXES TESTED IN TWO ORDERS

Test order	Avoidances (out of 50)		Latencies (sec)	
	Males (mean \pm S.D.)	Females (mean \pm S.D.)	Males (mean \pm S.D.)	Females (mean \pm S.D.)
Open field-avoidance conditioning	34.2 \pm 12.1	33.6 \pm 12.6	4.3 \pm 1.83	4.3 \pm 1.92
Avoidance conditioning—open field	39.1 \pm 12.7	26.8 \pm 14.5	3.2 \pm 1.27	5.5 \pm 2.47

to the controls but not to the gestational stress group; these two latter groups do not differ significantly. The analyses of variance of both scores also show an effect unrelated to pre-natal treatment. This was a significant sex \times test order interaction (avoidances: $F = 6.76$, $P < 0.025$ with 1, 27 d.f.; latencies: $F = 8.57$, $P < 0.01$ with 1, 27 d.f.). The relevant means, contained in Table 2, show that males perform better if tested in the shuttle box prior to the open field, whereas with females prior experience in the open field leads to improved avoidance conditioning.

Analysis of the open-field ambulation scores revealed no significant effects other than the usual sex differences, with females ambulating more than males. Defaecation scores were not analysed since, as might be expected from their constitutional background, only three of the 48 MNR subjects defaecated.

There were no significant differences in the weights of the foster-offspring at any age as a function of either maternal strain or experience.

It seems unlikely that the effects which were detected were mediated by changes in the emotionality of the foster-mothers resulting from the pre-natal treatments, since there were no differences in offspring behaviour as a function of the foster-mothers' strain although the strains differ markedly in emotionality, the characteristic for which they have been bidirectionally selected. While the treatments imposed did affect the foster-mothers' emotionality, as detected by testing in the open field prior to the experiment and again after the litters were weaned, the nature of the results does not especially correspond to the effects on the avoidance conditioning of the litters they reared. There were strain differences in the direction of the effects of the different treatments on ambulation scores (strain \times treatment interaction: $F = 10.63$, $P < 0.005$), with pre-mating stress resulting in the smallest increase in ambulation among MR females, all groups of which showed an increase, and gestational stress resulting in the smallest decrease among MNR females, all groups of which showed a decrease. Defaecation scores showed some increase on re-test but were not analysed, again because of zero MNR scores.

This investigation indicates that subjecting female rats to stress in maturity affected the adult avoidance conditioning but not the emotionality of the foster-offspring which they reared. The strain of the foster-mothers did not of itself affect the adult behaviour of the offspring. It confirms previous work^{3,4} in its general finding that conditions to which an organism is exposed can modify the behaviour of offspring which it rears. In thus showing that maternal experience in maturity can influence the behaviour of foster-offspring, it further indicates the necessity of using some method of controlling the post-natal maternal environment in experiments on pre-natal stress if the effects on offspring in such experiments are to be validly attributed to the pre-natal period; to do otherwise is to run the risk that the mothers' pre-natal experiences may affect offspring behaviour post-natally.

A full account of this and related work is being prepared for publication elsewhere⁷.

This work was supported by a grant from the Maudsley and Bethlem Royal Hospitals Research Fund. I thank Prof. P. L. Broadhurst and Prof. J. L. Jinks for their advice.

FORTHCOMING EVENTS

(Meetings marked with an asterisk are open to the public)

Monday, November 22

ROYAL GEOGRAPHICAL SOCIETY (at 1 Kensington Gore, London, S.W.7), at 5 p.m.—Major N. J. D. Prescott, R.E.: "The Geodetic Satellite—SEGOR".

UNIVERSITY OF LONDON (at the London School of Hygiene and Tropical Medicine, Keppel Street, Gower Street, London, W.C.1), at 5.30 p.m.—Prof. H. Braunsteiner (Innsbruck): "Clinical Significance of Triglyceride Determinations, Especially in Relation to Age, Body Weight, Different Forms of Diabetes and Thyroid Disease".

ROYAL SOCIETY OF ARTS (at John Adam Street, Adelphi, London, W.C.2), at 6 p.m.—Prof. Colin Cherry: "The Communication Explosion". (Second of three Cantor Lectures on "World Communication".)

SOCIETY FOR VISITING SCIENTISTS (at the English Speaking Union, Dartmouth House, 87 Charles Street, London, W.1), at 7.30 p.m.—Discussion Meeting on "The Retrieval of Scientific Information". Chairman: Dr. H. T. Hookway. Speakers: Prof. H. Kaiser, Dr. W. Batten and Mr. A. St. Johnston.

Monday, November 22—Tuesday, November 23

INSTITUTION OF ELECTRICAL ENGINEERS, ELECTRONICS DIVISION (at Savoy Place, London, W.C.2)—Conference on "U.H.F. Television".

Monday, November 22—Friday, November 26

INSTITUTE OF METALS (at the Royal Commonwealth Society, Craven Street, London, W.C.2)—Third International Conference on "Plutonium".

Tuesday, November 23

SOCIETY OF CHEMICAL INDUSTRY, AGRICULTURE GROUP (at 14 Belgrave Square, London, S.W.1), at 10.30 a.m.—Meeting on "Chemicals in Animal Nutrition".

UNIVERSITY OF LONDON (at Westfield College, Kidderpore Avenue, London, N.W.3), at 5.15 p.m.—Prof. D. H. Wilkinson, F.R.S.: "Elementary Particles".

INSTITUTION OF CIVIL ENGINEERS (at Great George Street, Westminster, London, S.W.1), at 5.30 p.m.—Informal Discussion on "Use of Slag in Road Building", introduced by Mr. R. A. Kidd and Mr. R. T. Jackson.

UNIVERSITY OF LONDON (at the London School of Hygiene and Tropical Medicine, Keppel Street, Gower Street, London, W.C.1), at 5.30 p.m.—Prof. W. G. Spector: "The Cytokinetics of Chronic Inflammation". (Eighth of fifteen lectures on "The Scientific Basis of Medicine" organized by the British Postgraduate Medical Federation).*

INSTITUTION OF CHEMICAL ENGINEERS, SOUTH EASTERN BRANCH (at the Royal Aeronautical Society, Hamilton Place, London, W.1), at 6 p.m.—Mr. C. J. Stairmand: "Gas Cleaning".

ROYAL METEOROLOGICAL SOCIETY (in the Conference Hall, County Hall, London, S.E.1), at 6 p.m.—Dr. D. G. James: "The Use of Satellite Observations in Meteorology".

INSTITUTION OF MECHANICAL ENGINEERS, GRADUATES' AND STUDENTS' SECTION (at 1 Birdcage Walk, Westminster, London, S.W.1), at 6.30 p.m.—Mr. D. Squires: "Blue Streak".

SOCIETY OF CHEMICAL INDUSTRY, PLASTICS AND POLYMER GROUP (at 14 Belgrave Square, London, S.W.1), at 6.30 p.m.—Prof. A. Hopff (Swiss Federal Institute of Technology, Zurich): "Studies on New Polymers and Monomers".

SOCIETY FOR ANALYTICAL CHEMISTRY, SPECIAL TECHNIQUES GROUP (at the Chemical Society, Burlington House, Piccadilly, London, W.1), at 7 p.m.—Annual General Meeting, followed by Dr. L. Brealey: "Some Analytical Problems in the Power Generating Industry".

Tuesday, November 23—Wednesday, November 24

INSTITUTION OF GAS ENGINEERS (at Church House, Westminster, London, S.W.1), at 9.15 a.m. on Tuesday and 9 a.m. on Wednesday—31st Autumn Research Meeting.

Wednesday, November 24

UNIVERSITY OF LONDON (at the Postgraduate Medical School of London, Du Cane Road, London, W.12), at 2 p.m.—Dr. G. W. Ashcroft: "Aspects of the Cerebral Metabolism of Tryptophan".*

GEOLOGICAL SOCIETY OF LONDON (at Burlington House, Piccadilly, London, W.1), at 5 p.m.—Dr. G. A. Chinner: "The Distribution of Pressure and Temperature during Dalradian Metamorphism".

ROYAL STATISTICAL SOCIETY (at the London School of Hygiene and Tropical Medicine, Keppel Street, Gower Street, London, W.C.1), at 5.15 p.m.—Discussion on "The National Plan" opened by Mr. W. Beckerman and Mr. K. J. Wigley.

INSTITUTE OF FUEL (at the Royal Institute of British Architects, 66 Portland Place, London, W.1), at 5.30 p.m.—Mr. W. G. Cummings, Mr. M. W. Redfern and Mr. W. Roberts Jones: "Air Pollution by Sulphur Dioxide".

INSTITUTION OF ELECTRICAL ENGINEERS, POWER DIVISION (at Savoy Place, London, W.C.2), at 5.30 p.m.—Mr. P. Honey: "Electric Water-Heating Development".

UNIVERSITY OF LONDON (at Senate House, London, W.C.1), at 5.30 p.m.—Sir David Cuthbertson, C.B.E.: "The World Protein Problem".*

INSTITUTION OF ELECTRONIC AND RADIO ENGINEERS, JOINT I.E.R.E./I.E.E. COMPUTER GROUPS (at 9 Bedford Square, London, W.C.1), at 6 p.m.—Mr. G. J. Crask and Mr. S. F. Miles: "Analogue Circuit Techniques Using Transistors".

INSTITUTION OF MECHANICAL ENGINEERS (at 1 Birdcage Walk, Westminster, London, S.W.1), at 6 p.m.—Mr. C. Seppel: "The Development of the Industrial Gas Turbine".

INSTITUTE OF INFORMATION SCIENTISTS (at the Whitehall Hotel, Bloomsbury Square, London, W.C.1), at 6.15 p.m.—Mr. C. W. Hanson *et al.*: "Report on the F.I.D. Conference at Washington".

SOCIETY OF CHEMICAL INDUSTRY, FOOD GROUP (at 14 Belgrave Square, London, S.W.1), at 6.15 p.m.—Mr. A. Lennard: "Odour in Packaging

Materials"; Mr. K. W. Taylor: "Hydraulic Conveying of Particulates in Narrow Bore Pipes"; Mr. E. L. Starkie: "Conversion of Malt Mash in a Plug Flow Converter".

SOCIETY FOR ANALYTICAL CHEMISTRY, MICROCHEMICAL METHODS GROUP (at "The Feathers", Tudor Street, London, E.C.4), at 6.30 p.m.—Discussion Meeting on "The Optimal Environment for Microanalysis", introduced by Mr. A. J. Cross.

Thursday, November 25

UNIVERSITY OF LONDON (in the Anatomy Theatre, University College, Gower Street, London, W.C.1), at 1.15 p.m.—Dr. F. B. O'Connor: "Soil Animals".*

INSTITUTE OF PETROLEUM, EXPLORATION AND PRODUCTION GROUP (at 61 New Cavendish Street, London, W.1), at 5.30 p.m.—Prof. Irving Fatt (University of California): "Microscopic Heterogeneity in Reservoir Rock and its Influence on Reservoir Behaviour".

INSTITUTION OF ELECTRICAL ENGINEERS, CONTROL AND AUTOMATION DIVISION (at Savoy Place, London, W.C.2), at 5.30 p.m.—Discussion on "Discrete versus Continuous Formulations in Control Theory" opened by Dr. A. T. Fuller, Dr. P. E. W. Grensted, Prof. E. I. Jury, and Prof. C. Storey.

ROYAL INSTITUTION, LIBRARY CIRCLE (at 21 Albemarle Street, London, W.1), at 5.30 p.m.—Mr. C. A. Cade: "Witchcraft—Delusion, Deception or Devilry?"

UNIVERSITY OF LONDON (at the London School of Hygiene and Tropical Medicine, Keppel Street, Gower Street, London, W.C.1), at 5.30 p.m.—Prof. M. D. Milne: "Cystinuria 1810–1965". ROYAL SOCIETY OF ARTS (at John Adam Street, Adelphi, London, W.C.2) at 6 p.m.—Prof. Colin Cherry: "The Future of World Communication" (Last of three Cantor Lectures on "World Communication".)

ROYAL SOCIETY OF MEDICINE (at 1 Wimpole Street, London, W.1), at 6 p.m.—Prof. R. H. S. Thompson: "A Biochemical Approach to the Problem of Multiple Sclerosis" (Jephcott Lecture).

INSTITUTION OF ELECTRICAL ENGINEERS, LONDON GRADUATE AND STUDENT SECTION (at Savoy Place, London, W.C.2), at 6.30 p.m.—Symposium on "Control and its Applications".

PLASTICS INSTITUTE, LONDON SECTION REINFORCED PLASTICS SUB-GROUP (at the Wellcome Building, Euston Road, London, N.W.1), at 6.30 p.m.—Mr. B. A. Clark and Mr. D. F. Failey: "Some Aspects of Design and Construction of Reinforced Plastic Building Panels".

ROYAL GEOGRAPHICAL SOCIETY (at 1 Kensington Gore, London, S.W.7), at 8.15 p.m.—Mr. A. R. Hanbury-Tenison: "From the Orinoco to the Plate".

APPOINTMENTS VACANT

APPLICATIONS are invited for the following appointments on or before the dates mentioned.

LECTURER (with suitable academic qualifications and relevant experience) IN METALLURGY—The Principal, Lanchester College of Technology, Priory Street, Coventry (November 26).

JUNIOR RESEARCH ASSOCIATE (with a good honours degree in veterinary or agricultural science or biochemistry) IN AGRICULTURAL BIOCHEMISTRY,

for investigations into the mineral requirements of pigs—Head of the Department of Agricultural Biochemistry, School of Agriculture, University of Newcastle upon Tyne, Newcastle upon Tyne, 1 (December 1).

LECTURER or ASSISTANT LECTURER IN THE DEPARTMENT OF MATHEMATICS—The Secretary, The University, Edinburgh (December 1).

EXPERIMENTAL OFFICER IN THE DEPARTMENT OF CHEMISTRY IN THE FACULTY OF SCIENCE to work on an electron spin resonance instrument shortly to be installed in the Department and concerned with the study of inorganic complexes—The Registrar, The University, Manchester, 13 (December 4).

LECTURER or ASSISTANT LECTURER IN THE DEPARTMENT OF MATHEMATICS—The Secretary, The University, Aberdeen (December 4).

LECTURER or ASSISTANT LECTURER (Probationary) (man or woman graduate with special interests in the field of logic or the theory of sets) IN MATHEMATICS—The Secretary, Bedford College (University of London), Regent's Park, London, N.W.1 (December 4).

LIBRARIAN—The Secretary, University of Stirling, Academic Planning Board, Municipal Buildings, Stirling (December 4).

LECTURER (with high academic qualifications and the ability and desire to pursue research) IN INORGANIC CHEMISTRY—The Principal, Lanchester College of Technology, Priory Street, Coventry (December 6).

OFFICIAL FELLOW AND TUTOR IN PURE MATHEMATICS—The Master, St. Catherine's College, Oxford (December 6).

TEMPORARY LECTURER IN PHILOSOPHY—The Registrar and Secretary, University of Durham, Old Shire Hall, Durham (December 6).

CHIEF TECHNICIAN (with sound qualifications, a knowledge of modern techniques, and preferably some experience and interest in administration) IN THE DEPARTMENT OF ZOOLOGY—The Secretary, The University, Highfield, Southampton (December 7).

LECTURER IN THE DEPARTMENT OF ZOOLOGY, University of Ibadan, Nigeria—The Inter-University Council, 33 Bedford Place, London, W.C.1 (December 7).

SENIOR LECTURERS, LECTURERS or ASSISTANT LECTURERS (2) (preferably with a special interest in one or more of the following: vertebrate zoology, invertebrate zoology, parasitology or physiology) IN ZOOLOGY at the University of Zambia—The Inter-University Council, 33 Bedford Place, London, W.C.1 (December 10).

LECTURER (with qualifications in the teaching of geography) IN EDUCATION—The Registrar, The University, Manchester, 13, quoting Ref. 198/65 (December 11).

READER, SENIOR LECTURER, LECTURER and an ASSISTANT LECTURER (suitably qualified candidates with interests in mechanical, civil, electrical, electronic, production or chemical engineering, or in engineering design) IN THE SCHOOL OF ENGINEERING SCIENCE—The Registrar, University of Warwick, Coventry, Warwickshire (December 11).

RESEARCH FELLOW IN PHILOSOPHY—The Rector, Lincoln College, Oxford (December 11).

CHAIR OF BIOCHEMISTRY—The Secretary, The Queen's University, Belfast, Northern Ireland (December 15).

LECTURER/SENIOR LECTURER IN PURE MATHEMATICS at the University of Sydney, Australia—The Association of Commonwealth Universities (Branch Office), Marlborough House, Pall Mall, London, S.W.1 (Australia and London, December 17).

PROFESSOR OF THE HISTORY OF PHILOSOPHY—The Registrar, University Registry, Oxford (December 23).

CHAIR OF PHYSICAL CHEMISTRY at Victoria University of Wellington, New Zealand—The Association of Commonwealth Universities (Branch Office), Marlborough House, Pall Mall, London, S.W.1 (New Zealand and London, December 31).

LECTURER or ASSISTANT LECTURER (with interests in inorganic chemistry, physical chemistry, or theoretical chemistry) IN CHEMISTRY—The Registrar, University of East Anglia, Earlham Hall, Norwich, NOR 88C (December 31).

LECTURER (with a doctorate or equivalent research experience, and preferably specialist in the field of hard-rock petrology) IN GEOLOGY at the University of Newcastle, New South Wales, Australia—The Association of Commonwealth Universities (Branch Office), Marlborough House, Pall Mall, London, S.W.1 (January 1).

MARY MARSHALL AND ARTHUR WALTON CHAIR OF THE PHYSIOLOGY OF REPRODUCTION—The Registry, University Registry, The Old Schools, Cambridge, marking envelope "Confidential" (January 10).

HEAD (experienced soil scientist) OF THE SOIL SURVEY OF ENGLAND AND WALES—The Secretary, Rothamsted Experimental Station, Harpenden, Herts (January 15).

KNIGHTBRIDGE CHAIR OF PHILOSOPHY—The Registry, University Registry, The Old Schools, Cambridge, marking envelope "Confidential" (January 17).

DIRECTOR OF THE UNIVERSITY COMPUTING CENTRE—The Assistant Registrar (Establishment), University of Sussex, Stanmer House, Stanmer, Brighton, Sussex.

LECTURER (with good academic qualifications and experience in systems programming and/or computing in industry) IN COMPUTING—The Registrar, Regional College of Technology, Leicester.

POST-DOCTORAL ASSISTANT IN INORGANIC CHEMISTRY—The Secretary, Department of Chemistry, St. Salvador's College (University of St. Andrews), St. Andrews, Fife, Scotland.

PRINCIPAL (with high academic and professional qualifications)—Clerk to the Governing Body, Borough Polytechnic, Borough Road, London, S.E.1.

TECHNICAL OFFICER (with a degree in agriculture or related sciences or equivalent qualifications, and preferably experience in field experiments) FOR ROOT AND FODDER CROP TRIALS—The Secretary, National Institute of Agricultural Botany, Huntingdon Road, Cambridge.

Progress in Spectroscopy

Unicam SP800 Spectrophotometer with automation accessories

*Save operator time, increase speed
and efficiency with Unicam
automation for:*

ENZYME REACTION RATES

**LIQUID COLUMN
CHROMATOGRAPHY**

**ALL ROUTINE ULTRAVIOLET
& VISIBLE SPECTROSCOPY**

Send for descriptive brochure.

Among the many important applications for the Unicam SP800 Spectrophotometer none is a better example of its potential than the measurement of enzyme reaction rates. For this the Automation Accessories are vital components. Other widely acclaimed features are the Flat Bed Recorder, the Beam Balance Smoothing Cam and the unique Second Sample Position, all of which mark the SP800 as the outstanding U.V. and Visible Recording Spectrophotometer. The Automatic Equipment provides:

AUTOMATIC interchange of up to 4 sample and 4 reference cells,
AUTOMATIC re-cycling over any pre-selected wavelength range,
AUTOMATIC recording at predetermined time intervals.

TAB/DO.13A

BCM 200 REFRACTORY CUTTING MACHINE

HIGH SPEED PRECISION CUTTING OF REFRACTORIES, ROCKS AND CERAMICS

Cutting Disc Diamond Impregnated 14" dia.
Max. depth of cut $4\frac{3}{4}$ ".

Table mounted on vee guide rollers fitted with
needle roller journal and thrust bearings.

Area 11" x 17", with tee slots for clamping.

Table traverse 16".

Mitre rest and work clamp fitted to table.

- Spindle fitted with taper roller bearings.

Fully protected from abrasive sludge.

Vibration free drive powered by $1\frac{1}{2}$ horse
power motor. All electrics totally enclosed
in pedestal.

Coolant mainwater or soluble oil.

Finish Grey Stove Enamel.

- Adjustable Vise unit for controlled thickness
slicing.

- Reversible core vise for parallel facing of cores.

JACK BRIMBLE

A BOOK review in *Nature*, March 22, 1930, includes the following passage: "But these phenomena [growth and tropic movements of plants], like all others, demand an *ultimate exposition of the truth* [our italics]. This can never be cloaked, as an ideal, however enthusiastic one might become over a certain theory. One feels, therefore, to do this, we should strive for it in as simple a way as possible". This, in a nutshell, was what science meant to the reviewer, L. J. F. Brimble, and it remained so all his life—an ultimate exposition of the truth. These words of a new reviewer to *Nature* caught the eye of the then editor, Sir Richard Gregory. Thinking at the time that he required a second assistant, Sir Richard entered into correspondence with the reviewer and eventually invited him to London and to an assistant editorship of *Nature*.

Lionel John Farnham Brimble was born the son of a much-respected Somerset family on January 16, 1904. His early days in Radstock were happy ones, for he always cherished their memories. The family was an important unit to him—a view which he always maintained.

One of the factors which decided his later career was an innate curiosity of all that surrounded him. So strong was this that he rejected a scholarship to a Naval college and instead became a boarder at the nearby Sexey's School, Bruton. It was his great fortune that the headmaster of this school was far-sighted, and realized that science should be taught from a very early age. Not only were there science classes, but for those who wished, tuition was available in botany. In this respect Sexey's School was unique in the country. Botany was taught in a few girls' schools, but it was not, at that time, generally held to be a subject suitable for young men. Soon, with his natural abilities at drawing and sketching and his good knowledge of natural history gained from the surrounding countryside, his career was mapped out. He won a scholarship to the University College of Reading. There, where he read botany under Prof. W. Stiles, he proved himself an excellent field botanist and developed a particular interest in trees. Reading at that time was very much based on the Oxford College system, and for Brimble this was just the right kind of stimulation. His college friends remember how much he enjoyed the 'go' and gaiety of student life. He graduated at the time when Reading gained university status: prior to this, graduates had taken London degrees, but those who took their degrees at the time of the granting of the charter were awarded both London and Reading degrees. There being no science honours graduates whose names began with 'A'—or so far as the 'Bo's'—it was always Brimble's boast that he was the first to gain a B.Sc. (Reading). Brimble—or 'Jack' as he was now known to all his friends—was offered a research scholarship in Germany. Simultaneously a post of lecturer in plant physiology became available in the Department of Botany, University of Glasgow, under Prof. J. M. F. Drummond. By now something had clicked in his mind; pure research was not for him: he had a taste for gregarious living. Glasgow offered a post for both teaching and research. In 1926 perhaps the youngest science lecturer in the country arrived at Glasgow.

The prospect of having to lecture to eighty pre-clinical medical students, the majority of whom were much older than he, would have paled most, but not Jack Brimble. It was his personality that won through, and staff and students alike greatly appreciated the jollity of his character. He was an excellent, kind teacher who liked, and was liked by, his students. He had a fine sense of humour, an agreeable voice, and an infectious enthusiasm which made him bob up and down. He stayed but a year in Glasgow, being offered a lectureship in the University of Manchester, where he stayed from 1927 until the end of 1930. His research was very much in the Stiles idiom, namely, physiological research on ion exchange in tissues. However, his research ideas never underwent any great or imaginative developments. He was just not made that way, but he knew what he wanted. His days at Manchester were exciting, in that he could satisfy his deep love of music by listening to the Hallé Orchestra under Sir Hamilton Hartley. He had many literary friends and in his spare time was a theatre critic on a local paper. It was while he was at Manchester that he was approached by the Editor of *Nature* to review the book by Sir Jagadis Chunder Bose, *Growth and Tropic Movements of Plants*.

On reading the review, Sir Richard realized that here was someone who saw science as more than just his own speciality. Each man's work was only part of a greater all-encroaching pattern. Brimble showed that he firmly grasped the basic concept that lay behind the 'philosophy of science' and, at the same time, could put over his ideas. All this, coupled with his personality, fitted him for the work that lay ahead. Brimble, without really knowing why, and to the horror of his family, abandoned his academic life for an 'office life'—or so some thought—and joined *Nature* as an assistant editor to Sir Richard in 1931. Contrary to those who thought this move a mistake, his new role gave him the special opportunity to develop his innate needs and qualities—to write, to meet people and to have a wide awareness of what was going on, not only in the world of science, but also in the world of expanding education and educational beliefs. At heart Jack Brimble was an educator. While in many ways he and Sir Richard were unlike, in others they saw eye to eye very closely. He very soon became a disciple of Sir Richard, who encouraged his wide outlook and catalysed his exuberance. He remained throughout his life enthusiastic, but he never allowed enthusiasm to affect his judgment. *Nature* and belonging to the House of Macmillan gave him many outlets which he greatly enjoyed. For to know the activities of the changing world and what was going on in it was his *métier*. He enjoyed all this, partly as the fun of life, but also as an opportunity for exercising his developing flair for scientific news. However, behind all this there was a great fund of common sense and a surprising shrewdness in the business aspect of his profession. He was faithful 'to his salt', to the integrity of science, to the great and honourable traditions of *Nature*, and to the old and distinguished publishing House, for which he had deep respect.

Jack Brimble remained a true botanist, that is, a lover of plants as perceived by human kind, as an artistic entity

and as an inspiration of poetry and folk-lore. In such approaches to botany he was an unsurpassed contemporary exponent: hence the success of his better-known books, particularly *Flowers in Britain*, *Trees in Britain* and *The Floral Year*. His love of good illustrations and his personal delight in drawing were features of his work. Didactically, his *Intermediate Botany* had a very considerable success, partly because he understood so clearly the educational need for such a book, but in no small measure because the book was so well planned and comprehensive. Not all his books escaped critical review. He always delighted in relating his cruel experience of editing an adversely critical review of one of his own books, for publication in his own journal, and how he had to resist the temptation to 'blue-pencil' that which he thought unfair.

In the late 'thirties he was associated with the movement then afoot to develop the teaching of biology in schools (even at that time it was still restricted mainly to botany in girls' schools). Later he was involved with the organization of the British Social Hygiene Council, which eventually became the Central Council for Health Education. His associates included Sir Julian Huxley, Prof. Winfred Cullis, Prof. J. B. S. Haldane, the memorable Mrs. Neville Rolf and Sir Robert Fields. He, with many others, wrote articles, gave lectures, held courses at summer schools, organized brains-trusts and in general did much to promote these causes.

In 1938, on the retirement of Sir Richard, Jack Brimble and his colleague A. J. V. Gale were appointed joint editors of *Nature*. Thus began a new chapter in the history of the journal. The partnership was a fruitful one which was to last twenty-three years, to carry *Nature* through the Second World War into a realm of new science expanding exponentially on all frontiers. With this partnership the traditions which Sir Richard had built up were maintained and developed. This was especially so in encouraging the work of the British Association for the Advancement of Science. Brimble, like Gregory, was keen on focusing interest on social relations. He became involved in army education under Major-General Walter Beddall and Major-General Cyril Lloyd, and during the War lectured in many parts of the country to various Commands. His book on the social aspects of science, with its references to teaching, good Government, public and individual health, was a pioneer for much which has since been written. His visits abroad, both to collect information and to give it, were of lasting importance. His visit to Cairo was largely responsible for transforming the science facilities and teaching at the University (he was also responsible for quelling an anti-British student riot by threatening to cancel his lecture—such was the esteem in which he was held). Much the same may be said about his visit to India and later Malta where he was a member of the Royal University of Malta Commission. Certainly his liberal outlook was well ahead of his time.

It was always a great disappointment to Jack Brimble that he was not allowed to enter the Navy. He would dearly have liked to have served in submarines, but time after time he was rejected. Because he was unable to play an active part in the War, he made up for it by organizing the local fire-watch. It was for his generosity and cheerful personality in such trying times that he endeared himself to many in the London W.C.2 area and especially to the staff of Macmillans. He was appointed organizing warden of the local section. Besides the men who worked in the vicinity of his ward there were many

ladies (including some of renown). Although a general ruling had been given that men and women alike must undertake fire-watching, he broke this by never allowing the ladies to do so.

Jack Brimble quickly perceived that, because of the kind of gloom and misery that remained after the War, people were looking for something else. It was then that he strove forward with his *In Britain* series of books. He sensed that people were really recoiling from all the truth of war: he endeavoured to bring some light into life. He realized in 1944 that if we attained our objective in winning the Second World War, the Butler Education Act would need much more financial backing. He was instrumental in organizing and preparing leading articles which eventually led to the Government writing in an extra £8 million. Besides this, he did a great deal to direct the attention of men of science to the development of education during the Butler Act.

He had a deep respect for the dignity and integrity of the Press. With his usual enthusiasm he took it on himself to encourage the interpretation of science to the general public, and in many ways his own public lectures set the pace. A fund of anecdotes to suit any occasion (he never told 'jokes' in any of his public addresses, although he had, for private ears, an inexhaustible repertoire) ensured that his lectures were always lively: but there was a shrewd message in them, and he was never afraid to speak out against anything that he considered unprincipled. To him, an editor's ideas should not be opinionated, but reasoned and based on intuition instilled from experience.

Brimble always accepted the saying that 'a good editor wears out the soles of his shoes before the seat of his pants'. He developed through his visits a particular wealth of American and Australian friendships. He had perceived the great advances that American science was to make, and that to a large extent it would set the pace. He fruitfully strove to cultivate good relationships between the United Kingdom and the United States, and to steer them on a steady course. To do this, it had to be openly displayed that *Nature* made every effort to be dispassionate and objective; differences between race, colour, nationality, creed or political views were allowed no scope whatever.

Jack Brimble's health deteriorated in the late 'fifties, but he never outwardly allowed this to cloud his life. He suffered periodically from a wound received during the Blitz of London. But, by now, his dedication to the journal was so intense that he took little relaxation. Such dedication did not just stop at the material journal, but included all those associated with it, and it inspired a like dedication in all of them. No man could have treated his staff better than he did. Nothing was too much for him; if he had a problem he would play with it for hours, looking at it one way, then the other. He was a kindly, gentle human being, with great human sympathies which he did not parade overtly. To him the most important thing was 'people'. He compulsively involved himself with people, sharing their troubles and their elations.

At the end of 1961, A. J. V. Gale retired from the joint editorship, leaving Jack Brimble as sole editor. Even though the editorial staff had been depleted, he strove to increase the size of the journal. This meant more work for him, and typically he would say, "Oh well, have to make to-morrow a twenty-five hour day". But he had in very large measure the most vital attribute of a great editor—

an ability to select deftly (often with almost uncanny intuition) those items worthy of *Nature*. He never tired of discussing his plans and ambitions for the future, in which the tradition and the progress of *Nature* would be maintained without faltering.

In his inaugural address following his election to the Royal Society of Edinburgh in 1953—of which he was justly proud—he stated that no material for publication in *Nature* came from the U.S.S.R. and only a little from its satellites. The trend in the early 'sixties has been that material has flooded in for publication from the U.S.S.R. and its satellites. This was part and parcel of his deliberate policy to encourage the submission of material from the Eastern bloc. Similarly, he concentrated on the advancement of the emergent countries, offering all the encouragement and help possible in publication.

Jack Brimble lived long enough for the journal to reach its 5,000th issue on August 28, 1965. That he was not ostentatious and was still proud of his West Country lineage and accent was obvious to all who saw his B.B.C.2 interview at this time.

Jack Brimble's life, which came to a close on November 15, was dedicated to the editorship of *Nature*; but he will be remembered by those scientists who knew him as a man even more than as an editor. His immediate impact was one of outgoing gaiety and generosity of spirit. First there was a hearty greeting, puckishly provocative ("You don't seem to have published much lately!") and offered with a sincerity which made it evident that he revelled in talk and the company of friends. Then came the ebullient phase—his mind was always bubbling over with some question of the day—gossip about the scientific world—shrewd and always entirely free from malice—about who ought to get this chair or that; who ought to have his head examined; who ought to be put on this committee; what ought to be done to improve the universities or the Research Councils or the British Association. So then to the third phase: what should *Nature* say about this? Has *Nature* drawn attention forcibly enough to this or that? Just beneath the scientific-man-about-town was the keen editor, always on the alert for news, ideas, opinions; able even in his boisterous moments to catch hold of a point of view and to make sure (if he thought the view worth preserving) that it was included in that constant scanning of the scientific scene which was his life's work and which made *Nature* the most remarkable scientific journal of its class in the world.

He came to look on the journal as being his life and always insisted that it belonged to the world of science.

GRASSLAND AND FODDER IN INDIA

The Grassland and Fodder Resources of India by R. O. Whyte. Revised edition. (Scientific Monograph, No. 22.) Pp. x+553+58 plates. (New Delhi: Indian Council of Agricultural Research, 1964.) Rs. 20.00.

THIS revised edition of *The Grassland and Fodder Resources of India* follows that first printed in 1957 and deals exhaustively with fodder resource problems under Indian conditions. Recommendations are made on

a wide variety of production methods. The twenty chapters are devoted to fodder supplies in relation to the present-day needs of Indian livestock and to ways and means of attacking the almost insoluble problem of feeding so many cattle on too little grass and other feeds. Emphasis is on the need for better-quality fodders; those presently available are extremely poor by any standard. Plant breeding, herbage, seed production and an account

of Indian soils and their fertilizer requirements are dealt with in separate chapters. Problems of conservancy and the related ones of pasture management are considered fully, as also are details of the feeding régimes used on Government or corporation farms. These, however, are much above average and bear little relation to those used in the Indian villages. This is clearly reflected in the much higher levels of production attained on, say, the military farms of India. Although details of milk yields are not given, there is the clear suggestion that at their best, and when adequately fed, the Indian breeds of dairy cattle produce on a par with European cattle. Frequent mention is made of the potential output of a reshaped dairy industry in India, but it would have added to the value of the argument if precise figures of yield (per cow and per acre) could have been included.

Throughout the book is the continued theme which emphasizes the problem of fodder in India as one where the primary need is to reduce the number of cattle so as to bring it into line with fodder supplies (actual and potential). Cattle are the backbone of Indian agriculture, and efficiency must be raised if prosperity is to come to rural India. Clearly nutrition is the key, but at present the cattle are underfed and hence the rather distressing (but realistic) call for reducing their numbers. However, there are religious problems which ultimately can only be solved by the Indian people themselves and this depends on the education of the masses. It is part of the Hindu philosophy to prohibit the killing of cattle, however worthless and however competitive with the human for food. This point bears repetition, even though it has always been the major concern of agricultural developers in India and is frequently repeated by those from other countries who visit the sub-continent.

A plea is made for more research and also for making available nation-wide statistics of sufficient accuracy on which sound rural planning can be based. In India, man, cattle, sheep, pigs and poultry are all in competition for too little food. The farms are too small, and even if it were possible to intensify production the problem would still remain; namely, how the cultivator with less than five acres can grow bread, corn and fodders sufficient to provide for his family, let alone produce a surplus. Part of this problem concerns levels of crop yield; the average cereal and pulse yields in India are about 600 lb. and 400 lb. per acre respectively; whereas on the Government farms, including the experimental and seed farms, these figures are quadrupled. As with the animals, the key is partly nutritional; the usual story of a need for both organic and inorganic fertilizers, including, in some cases, trace elements. At the present level of yield in all crops, the supply of animal feed provides less than one-fourth of the protein and two-fifths of the energy requirements of the bovine population.

Natural grasslands are infrequent on the Indian scene, but man-made 'grassland' occupies extremely large areas and is basic for the nutrition of cattle and sheep. Many attempts have been made to classify these grazing lands and there is at present in progress the Grassland Survey of India, in which the author of the monograph has taken a prominent part. Descriptive notes concerning a number of contrasting sites dealt with in the survey are given in Chapter 7, while in the preceding chapter a valuable record is made of botanical features of grassland in several regions. Most of these 'grasslands' represent interim (seral) stages between forest and desert; few appear to be climax stages.

The book is well illustrated and has a useful bibliography. The glossary of Indian terms is indispensable for the reader outside India. The production is of reasonably good standard, but the text is not without its typographical errors. The volume should have the interest of a wide audience of pasture and animal scientists and is of particular importance to all who live in densely populated regions within the tropics.

WILLIAM DAVIES

"THAT OLD COMMON ARBITRATOR, TIME"

The Psychology of Time

By Prof. Paul Fraisse. Translated by Jennifer Leith. Pp. vi+343. (London: Eyre and Spottiswoode (Publishers), Ltd., 1964.) 30s. net.

THE author of this painstaking work on an important subject is professor of experimental psychology at the Sorbonne. He has contributed 27 papers on various aspects of time in the bibliography of this work, which is a valuable source book. Its very numerous references, some 550, have a French and German slant, and even though supposedly revised recently, several important works (for example, Bünning, Gooddy, Harker, Whitrow, and the 1960 symposia at Warm Springs and at Würzburg) are missing. The translation by Jennifer Leith seems too literal and American ("time-structured behaviors") for the subtlety of the ideas of the author.

The Psychology of Time is divided into three parts, each prefaced by a summary of the ideas of the next few chapters. The sections are on "Conditioning to Time", "Perception of Time" and "Control over Time". Prof. Fraisse believes that "under the influence of periodic changes, the organism becomes a physiological clock which provides cues for temporal orientation both in animals and man". It is this ability to reproduce regular sequences that permits us to appreciate durations. It is perhaps in this way that animals adapt to change through "temporally organised behaviour". The section on time perception reviews a great deal of work on the perception of duration, which is summed up as "a function of our attitude". The final section, on the "Control over Time", some 130 pages long, assesses the advantages of man over other animals in being able to consider changes outside the immediate present; though how animals achieve awareness of any form of time is uncertain. We are told: "Animals do not, however, refer explicitly to past events in their behaviour; nor do they have a purpose". We are all animals, and we ourselves may not know about the purposes except of our own species, since the concept of purpose can be discussed only in human language.

The author states: "We live in the present". His theme is to show man's superiority in being able to 'control' past and future time. He also states that periods in the recent past seem longer than similar periods years ago, a statement in great contrast with the almost universal feeling that the times (and spaces) of childhood were so much larger, when later reviewed, than the adult now remembers them to have been. We must disagree with the author here, for we live in the future. Every thought and action is a scheme for the future based on the data of memory, poised on the ever-vanishing springboard of the present. If we did live in the present, both past and future, immediate or remote, would always escape us, memory would serve no purpose, and prediction, our main advantage over other animals, would never be achieved. There could be no perception, no action, no sequence, no language, no process of living. The sign of life is, in Goldstein's fine phrase, an "attitude towards the possible". The present is an extrusion, even an excretion, of nervous activity; and we use it only to check our position on the chart of our world-lines.

If this book is lacking in lucidity and perhaps in clear aim, it may be that the author has attempted too formidable a task, in a field which is only now even beginning to be isolated and defined. He makes us aware of a new realm for scientific exploration, where the thinker and investigator must possess exceptional qualifications in several, at present separated, branches of science. To be successful in that synthesis of ideas expressed by the word 'time', the broad scientific education must be enhanced by an almost superhuman intelligence and technique. Present-day education, with its wasteful

separation into separate streams of sciences and arts, trains the thinker to suppose that precision of meaning and clarity of expression in understandable language are too trivial for the experimentalist to learn. Thus literary expression may falsely seem effete, while private scientific languages prevent the intrusion of the 'simple' man, who is our chief study, into the deliberate abstruseness of scientific study. If we are to advance into the study of the various aspects of human behaviour which are subsumed under the code-word, the algebraic symbol, 'time', we must have a method of defining our objects and explaining our methods of reaching them. 'Time' is of the common man, and must always be studied in direct relation to his form and to his language. W. GOODDY

DOCUMENTATION

Some Fundamentals of Information Retrieval

By John R. Sharp. Pp. 224. (London: Andre Deutsch, Ltd., 1965.) 35s. net.

THIS book, by a librarian, is chiefly concerned with the ways in which documents can be classified or indexed so that they may be stored. This, of course, is merely the reverse of the process by which they may be recovered for consultation. It does not deal at all with storage of fact or with deductions from stored facts, so that fashionable glances at symbolic logic are not very relevant.

Perhaps the chief value of *Some Fundamentals of Information Retrieval* to working scientists is that it serves a warning of what may be in store for them unless they take a more active interest in what the librarians are proposing on their behalf. For one thing, a nasty jargon is being developed and the book is fairly typical of the sort of prose that may be expected now that librarians have moved into the computer belt. A reviewer in *The Times Literary Supplement* has characterized Mr. Sharp's style as 'rebarbative'. Having consulted the dictionary, I would agree with the adjective, which is defined as: crabbed, unattractive, repellent. Librarians are seldom accorded the importance or the salary that the essential nature of their work in a scientific organization warrants possibly they are now having their revenge.

It is true that the classification and indexing of documents is the most important step if the information they contain is to be processed by computer so that it can be recovered. The book certainly gives a good idea of the difficulties involved in this process. Mr. Sharp, who was senior indexer on the Association of Scientific Libraries and Information Bureaux (ASLIB) Cranfield Research Project, has obviously given a good deal of thought to the matter, and his own particular system, Selective Listing in Combination (it has one of those chi-chi abbreviations SLIC), depends on the indexer selecting five key words from the title or content of the paper and feeding these into the computer in all possible combinations in alphabetical order. This system puts at a disadvantage those words that come late in the alphabet.

As for retrieval, there is only very cursory discussion of the various machine procedures, and one of the most fundamental aspects of the matter is not discussed at all—this is a question of cost in time, labour and machinery. The book makes it clear that the indexing job is a skilled one and the final chapter on auto-indexing and auto abstracting suggests that it would be a long time before the machine can cope with this task. As editors are often lax about ensuring fully informative titles to papers, the indexer may well have to read a paper to decide what information it contains and in what form it should be stored. Obviously a staff of indexers must be enormous to cope with all relevant scientific papers in any particular field—and is the exercise really worth while? To industrial and commercial scientists the answer may well be yes and it is to these that Mr. Sharp's suggestions may be

fruitful—and his examples are indeed chiefly drawn from aeronautics and textile technology. The problem is not so acute to the academic scientist, who can usually scan the relatively few top journals in his own subject and these contain most of the best work. If the sea of the world literature is to be dredged for all relevant papers, a great deal of rubbish will come to the surface—the indexer cannot be a judge as well. This sceptical view is, of course, an extreme one. But scientists should be made aware of the problems involved and be sure that present bibliographic aids (scarcely mentioned in this book) have failed before they allow librarians into the driving-seat of a computer.

P. C. WILLIAMS

ENGINEERING APPLICATIONS OF RUBBERS

Rubber in Engineering Practice

By A. B. Davey and A. R. Payne. Pp. x+501. (London: MacLaren and Sons, Ltd.; New York: Palmerton Publishing Co., Inc., 1964.) 90s.

PERHAPS the strongest impression gained on perusing *Rubber in Engineering Practice* is of the remarkable variety and range of what may be broadly called the 'engineering applications' of rubbers—a term which includes not only engineering in the narrower sense, typified by engine mountings, couplings for power transmission and spring suspensions, but also such widely diverse uses as sound insulation in buildings, anti-vibration mountings for instruments, and packaging devices in sponge or other form. All these applications are dealt with in considerable detail, and while, no doubt, some selection must have been unavoidable, it is difficult to believe that any really important application has been omitted. As a source of information on what devices are available, therefore, this book is likely to be eagerly sought by engineers interested in this general field.

The book, however, is far from being a mere compilation, for in addition to its clear presentation, with a very large number of detailed drawings, of the various engineering components utilizing rubber in one form or another, it includes a general scientific introduction to the physical (and where necessary chemical) properties of rubbers, and the way in which these are applied in the design of engineering components. Starting from the basic types of deformation, shear, torsion and compression, it shows how these may be applied, and in many cases combined, to give a wide variety of spring characteristics to meet the many types of complex loading encountered. In addition to this, the basic mechanics of suspension systems, of the transmission and absorption of vibrations, including resonance phenomena, and, in general, of the response of coupled systems to oscillatory disturbances, is discussed. Some of this material has already appeared in an earlier book on this subject (*Engineering Design with Rubber*, by Payne and Scott).

Not unnaturally, a large part of the book is taken up with engineering applications in the narrower sense, and in this Davey and Payne have drawn heavily on the industrial experience of particular firms who have specialized in the production of engineering components. Even so, the operation of the many components depicted—some of remarkable ingenuity and subtlety of design—is fully discussed in the light of the scientific principles expounded in the first section, and good and bad features of design are brought out.

While rubber components such as shock absorbers and vibration insulators, particularly in connexion with transport vehicles, have been with us for a long time, the growing field of application in civil engineering is of more recent development. Surprising as it may appear at first sight, the use of rubber as a support for bridges is an example of an application in which this material has a clear technical advantage over alternative systems.

It is interesting to learn that such bridges as the Tancarville bridge across the Seine (960 m) and the St. Lawrence Harbour bridge, Canada (3 km), are supported on rubber, and it is stated that not one of the many natural rubber bridge bearings which have been installed during the past 10 years, so far as is known, has failed or shown signs of failure.

The least satisfying part of the book is probably the introductory part, in which the physical properties of rubbers are discussed. The impression is given that too much ground is being covered, and the presentation is not always as clearly thought out, or as precise, as might be desired. For example, Fig. 3.2 gives the erroneous impression that the stress-strain relations for rubber are linear for compressions up to 40 per cent, and for extensions up to 25 per cent (though the text makes it clear that this is not so). Again, there is confusion over the stress-strain relations derived from the statistical theory; Kuhn did not derive equation (3.2), and in the reference to his paper dealing with the properties of a bulk rubber (dated 1936, not 1934) it is not true to say that he considered only a single molecule; though not explicitly defining a cross-linked network of molecules, he adopted a simplified model in which one-third of the molecules were oriented parallel to each of the three co-ordinate axes, which, as has since been shown, is basically equivalent to the more general network treatment. Readers who are concerned with the basic physical properties of rubbers will need to supplement this account with additional reading.

Apart from this, the book succeeds in its purpose of presenting a broad general survey of the whole subject of the engineering aspects of rubbers, and can be confidently recommended.

L. R. G. TRELOAR

FAST BIOCHEMICAL REACTIONS

Rapid Mixing and Sampling Techniques in Biochemistry

Proceedings of the First International Colloquium on Rapid Mixing and Sampling Techniques Applicable to the Study of Biochemical Reactions, Philadelphia, July 23–24, 1964. Edited by Britton Chance, Rudolf H. Eisenhardt, Quentin H. Gibson and K. Karl Longberg-Holm. Pp. xii+400. (New York and London: Academic Press, 1964.) 72s.

PHYSICAL chemists have long been interested in rapid reactions, and E. F. Caldin has recently written a book concerned with their study in solution¹. Biochemists who work with bacteria also know that these cells catalyse quite fast reactions and that Macbeth might well have been making reference to experiments with such systems when he said: "If it were done when 'tis done, then 'twere well it were done quickly"; for if it is desired to show that, for example, ¹⁴C-acetate is converted initially into malate by a growing culture of *Pseudomonas* then all the samples should be taken within the first half-minute of the start of the experiment². One of the contributors to this symposium is J. A. Bassham, whose work with M. Calvin and others revealed the pathway of carbon in photosynthesis by a technique that involved rapid sampling of alga cultures; and with M. Kirk this author describes an application of this technique to follow changes in the photosynthetic carbon reduction cycle that occur when inhibitors are added. However, most of the other authors deal with methods more suited to the study of rapid reactions catalysed by enzymes in isolation, or to the rapid arrest of metabolism in muscle or liver. In general the biochemical results obtained are not discussed: the emphasis throughout is placed on the design of the apparatus used. Theoretical principles involved in the construction of apparatus are given in appendixes: thus, H. K. Wiskind gives examples of the application of fluid dynamics to the development of rapid mixing techniques, since one problem in the study of rapidly reacting compounds is clearly that of mixing them fast enough.

The typescripts of contributors to this book are reproduced exactly as received, and at the end of each the discussion provoked by the contribution is recorded verbatim. This procedure is now familiar; and as one who usually fails to start his newspaper at the point the editor considers to be most important, namely at the headlines, I usually read the discussions of such symposia first. Sometimes they instruct and entertain, but occasionally they do neither, as when the dialogue takes the form: "Doctor A: Did you try 'Versene'? Doctor B: No". In this particular symposium, dealing as it does largely with the design and use of apparatus, the discussions have maximum value because few experiences sharpen a scientist's critical powers more keenly than those entailed by the use of an imperfect machine. In the discussion on p. 116, Q. Gibson shows impressive graphs for apparent changes in concentration of a reactant during a reaction time of 0.7 sec; however, the stopped flow apparatus he used contained only distilled water and the measured changes in extinction were due simply to temperature gradients. Such discussions of artefacts and limitations of apparatus add to the value of this book, but there is a lighter side to some of the discussions as the following excerpt shows, taken from p. 269. "Chance: Oh, I thought our chairman would have been content to let sleeping sarcosomes lie . . . Davies: It is not the sarcosomes that lie."

The symposium is divided into two main sections: the first, rapid flow methods, and the second, rapid stopping and sampling techniques. There is a charming introduction to the first section in which F. J. W. Roughton traces the origins of rapid flow methods, and this is followed by four papers on rapid mixing and fluid flow, another four concerned with injection into a fixed volume, two on stopped flow and three on continuous flow methods. The last four papers of the first section relate to non-equilibrium situations created by exposure to a jump in temperature or to a flash of light, including photolysis due to a laser beam. The second section contains fourteen papers dealing with such methods as rapid freezing for interrupting muscular contraction and for metabolite assay in frozen samples of liver; and various pieces of apparatus are described by which it is possible to sample rapidly various systems ranging from yeast cells which are in the process of assimilating phosphate to mitochondrial suspensions metabolizing adenine nucleotides.

All biochemists faced with problems arising from the difficulties of measuring rapidly changing concentrations of metabolites will find sections of interest in this unique collection of papers by acknowledged experts in the field.

A WELL-BALANCED ACCOUNT OF THE ALGAE

The Biology of the Algae

By Dr. F. E. Round. Pp. vii+269. (London: Edward Arnold (Publishers), Ltd., 1965.) 36s. net.

ALL workers on algae, whether phycologists or workers in other disciplines using algae as tools, will undoubtedly be pleased to see an up-to-date text-book on the algae in the English language, particularly when so much information is condensed to give a well-balanced account in such a small volume.

The book contains 13 chapters, copious references and an adequate index. The first two chapters survey morphology, reproduction and life-history and include 10 pages of clear line drawings (an average of 21 drawings to a page) which will help students to visualize the overall picture of the form range in all the algal classes except the Rhaphidophyceae. This is a most valuable contribu-

tion, since only too frequently quite a high proportion of the algal classes are completely ignored for teaching purposes and students are left with the impression that there are only four or five classes of algae. Chapter 3 deals with cytology and genetics including especially the results of the more recent work on ultrastructure; five plates, in addition to line drawings, illustrate this section. The coverage, in the following two chapters, of algal ecology, both freshwater and marine, is well balanced and these sections include, in an excellently condensed form, a great wealth of information.

Physiology is considered at length in Chapters 6-10. The section on culture and nutrition deals with both major and minor elements and organic factors, while the following chapter, on energy sources and pigments, includes up-to-date information on the distribution of pigments in the algal classes. Chapter 8, entitled "Energy Relationships", gives a clear account of recent information on this subject. In Chapters 9 and 10 four subjects—movement, rhythm, polarity and morphogenesis—are adequately covered.

Chapter 11, on fossil algae and the deposition of calcium carbonate and silica, outlines the part that algae have played in geological history. Important data have been admirably summarized in the next chapter on the economic aspects. Here, the importance of algae in everyday life is emphasized by the inclusion of information on the use of algae as food, in agriculture, industry, medicine, sewage disposal, water purification, pollution and land reclamation.

In Chapter 13 the author has endeavoured to present clearly a most difficult subject which is still in a state of flux—algal taxonomy. This chapter has undoubtedly been recast to embody new information on certain classes and therefore there is some lack of agreement between the system of classification presented in Chapter 13 and that used throughout the rest of the text. For example, on p. 9 the class Dinophyceae includes the genera *Exuviaella* and *Prorocentrum*, whereas in the taxonomy of the author follows Fott and puts them in a separate class (p. 239), the Desmophyceae. Four points in this section should be noted: (a) the ending for a sub-division—phytina should be included in the list of endings (p. 227), as sub-divisions are used afterwards (pp. 235, 238), (b) the ending for a sub-order should be -ineae, not -inales (p. 227); (c) under Eucaryota seven phyla and one class are indicated (p. 230), but only seven phyla are dealt with, so presumably the Rhaphidophyceae (chloromonadines) must be the class lost by the wayside; (d) in the division Chrysophyta the first paragraph (p. 231) has not been revised to cover the modern concept of this division, since the author speaks of three classes whereas in the following pages he includes four classes in this division.

In spite of some minor defects this book will be most helpful both to phycologists and to workers in other fields. Its users will appreciate the enormous amount of information on methods given in the various sections; they will also find many suggestions for research problems incorporated, since the author has also indicated very clearly the gaps in our knowledge of the algae. Some misprints occur, mainly among the generic and specific names, but these are not serious. There are a few mis-statements, but these are not likely to mislead. For example, certain references to Fig. 14 on pp. 46-47 should read Pl. 4B and on p. 138 the author speaks of *Ilea* and *Actinococcus* being present around the St. Lawrence and the Bay of Fundy but being absent from the British coast. The *Ilea* = *Petalonia fascia* and *P. zosterifolia* and the *Actinococcus* = the nemathecium of *Phyllophora brodiaei*, all of which are recorded for the British coast.

This book is exceptionally good value for money, the illustrations are attractive and instructive, and Dr. Round is to be sincerely congratulated on the production of his book which satisfies a long-felt need.

MARY PARKE
G. T. BOALCH

DRUG-DEPENDENCE

By THE RIGHT HON. LORD BRAIN, F.R.S.*

WHEN I chose the present subject, I hoped that before I presented it the new report of the Inter-departmental Committee on Drug Addiction would have been published. However, it is still in the printer's hands, so I can say nothing about that now. When the report appears, however, as I hope it will soon, I believe it will be self-explanatory and call for no comments from me. The report of the earlier Committee, of which also I was chairman, raised a general question which seems to me important enough to call for further discussion. I can best explain this by quoting from the report. We said: "Most of our witnesses affirmed that, to-day, drugs acting on the central nervous system are being used excessively, but they were unable to furnish records in support of this contention". We obtained some information about the quantity of barbiturates prescribed annually in England and Wales over the previous two years and said: "It is obvious that usage has expanded both progressively and substantially so that, in 1959, it was almost twice what it was in 1951". We also stated that analysis of National Health prescriptions showed that "barbiturates, other sedatives and hypnotics, together with analgesics and antipyretics (excluding dangerous drugs), account for no less than about 19 per cent of all the prescriptions issued". There was also reason to believe that the prescription of tranquillizers had also increased, and we noted that the amount spent on one particular tranquillizer by nine selected mental hospitals had increased ten-fold over a course of five years. After mentioning the dangers of addiction to amphetamine and phenmetrazine, we noted that an analysis of some 214 million National Health Service prescriptions in 1959 indicated that some 5,600,000 or approximately 2.5 per cent were for preparations of the amphetamines and phenmetrazines.

Reviewing these facts, we made the following observations. "To explain this trend in medication directed at the central nervous system, we have found no single answer. In part it must be due to the vigorous advertising of these drugs and their preparations by the pharmaceutical industry, both to the medical profession and to the public. To some extent the accelerated tempo and heightened anxieties of modern life have been held to blame; but this is an assertion based on assumption more than fact. Thirdly, and possibly of considerable consequence, there is the materialistic attitude adopted nowadays to therapeutics in general. This is one feature of an age which owes so much to science. For every deviation from health, great or small, a specific, chemical corrective is sought and, if possible, applied, and it is also widely believed that health may be positively enhanced by the use of drugs. When dealing with mental disease, psychotherapy may still be invoked. Often, however, a prescription is given for a drug when the patient's real need is a discussion of his psychological difficulties with the doctor. An obvious danger arises when the drugs so employed, far from being placebos, are undeniably potent, frequently toxic, and sometimes habit-forming as well. On the other hand, the newer drugs are proving of great value in psychiatry where they are to some extent replacing other methods of treatment.

This increasing use of sedatives, stimulants and tranquillizers raises issues on which we do not as a Committee feel confident to pronounce. In particular, it is not for us to decide whether their occasional or even regular use is justified if it enables that person to lead a happier and more useful life. In any case, if resort to potentially habit-forming drugs is sometimes to be regarded as a symptom of psychological maladjustment, it should be treated as a symptom, and its cause sought, perhaps as much in social conditions as in the mind of the individual. These are questions which should be considered not only by doctors, but by all concerned with social welfare."

These are certainly difficult questions, and I do not propose to try to answer them all now. What I shall try to do instead is to clarify them, to look at their implications, and to suggest ways in which we may hope to contribute towards answering them. Basic to the whole problem are the meaning and implications of drug-dependence.

This term was introduced by the World Health Organization Expert Committee on Addiction-producing Drugs in their thirteenth report, published in 1964. In the fourth section, with the significant title "Terminology in Regard to Drug Abuse", it directs attention to some confusion which had arisen in the use of the term 'drug addiction' and 'drug habituation'. Because, it said, "the list of drugs abused increased in number and diversity" it sought a term which could be applied to drug abuse generally, and since "the component in common appears to be dependence, whether psychic or physical or both", it adopted the term "drug dependence", which it defined as "a state arising from repeated administration of a drug, often on a periodic or continuous basis. . . . Its characteristics will vary with the agent involved and this must be made clear by designating the particular type of drug-dependence in each specific case—for example, drug-dependence of morphine-type, of cocaine-type, of cannabis-type, of barbiturate-type, of amphetamine-type, etc.". In using the term 'drug dependence', and relating it to the abuse of drugs, it may seem that the World Health Organization Committee was only emphasizing the obvious; but my object is to suggest that the term 'drug abuse' itself raises some important questions which are not only unanswered but which we have not at present the knowledge to answer.

At least one valuable thing has emerged from the philosophy of the present century—its emphasis on the importance of words. So let us begin by asking what the word 'drug' means, and why it means what it does. *Webster's Dictionary* defines 'drug' as "any substance used as a medicine, or in the composition of medicine, for internal or external use", and then it goes on, "whether or not a given substance should be included under the term drug depends upon the purpose for which it is sold (as regards the seller) or used (as regards the purchaser)". So it would seem that the same substance may sometimes be a drug and sometimes not. When we get to the verb 'to drug' a new meaning creeps in, for Webster gives three definitions: "(1) to affect or season with drugs or ingredients; especially to stupefy by a narcotic drug; (2) to tincture with something offensive or injurious; (3) to dose to excess with or as with drugs". So a sinister

* Substance of the Address at the Inaugural Ceremony of the School of Pharmacy, University of London, delivered on October 13

note has already appeared: though we begin with drugs as any ingredients of a medicine, the average person hearing that someone has been 'drugged' would not imagine that he had been given penicillin. This is sometimes reflected in what patients will say to a doctor, for example: "I don't mind taking medicine, but I hope you won't put me on any drugs, doctor!" Or: "I hope that this is not a habit-forming drug". So far as the public Press is concerned, if you see the word 'drugs' in a headline you may be fairly sure that what follows refers to some sinister aspect of pharmacy, either 'drug-addiction' or the supposed danger of taking some particular drug or group of drugs. In the annual report of the Chief Medical Officer of the Ministry of Health, though there is a chapter called "Therapeutic Agents: Control and Toxicology", when reference is made to the possible dangers of therapeutic agents the word 'drugs' appears, and the relevant committee is called not a Committee on the Safety of Therapeutic Agents, but a Committee on the Safety of Drugs.

This pejorative meaning of the word 'drug' is relevant to this article, for the subject of drug-dependence is a highly emotional one. 'Drug addiction' hits the headlines frequently in the Press, and is the subject of plays and broadcasts. As a social problem, it excites an interest out of all proportion to its magnitude. In Great Britain, the total number of addicts to heroin, cocaine and morphine is well short of a thousand, and we are fortunate compared with Canada, where there are at least four thousand, and the United States where there are a great many more. But the number of men and women who will die of lung cancer this year in Britain is 25,000. Most of these are men in middle life. Their sufferings, the distress of their families and the loss to the community are collectively enormously greater than the effects of what is normally called 'drug addiction', yet these deaths excite no similar emotional interest, although they, too, are the indirect result of a form of drug addiction, addiction to cigarettes.

I am not a psychologist, and perhaps the psychologists can tell us why drug addicts to morphine, heroin and cocaine arouse such a disproportionate amount of interest; even without going very deeply into the matter, however, one may surmise that it is partly because these drugs are potent, mysterious and potentially dangerous: and one of their most mysterious characteristics is their power of temporarily or permanently changing the personality. Add to that the association of 'drug addiction' with crime and violence and we reach the conception of "potions . . . drunk of Siren tears, distill'd from limbeck's foul as hell within".

This is no exaggeration. The drug addict in this narrower sense is indeed a pathetic figure and a potentially dangerous one, too, if he or she becomes a source of infection to others. But, as the World Health Organization Committee recognizes, these drug addicts, though creating special problems, are only part of the broader spectrum of drug dependence.

It is obvious that there is nothing wrong with drug dependence as such. If a diabetic requires regular dosage of a drug to maintain his blood sugar at a normal level, or if a patient suffering from a collagen disease requires regular amounts of steroids, such patients are drug-dependent as already defined, their dependence being a physical one. But no one would describe this kind of drug-dependence as drug abuse: exactly the contrary. So it would seem that something more than mere drug-dependence is necessary to create drug-abuse, and if we look at the list of such drugs of both abuse and dependence which appears in the report of the World Health Organization Committee, I think the basis of the distinction becomes clear, for they are all drugs which are taken for their psychological effects. This brings us to the next stage of our enquiry, which is the crucial one. Is dependence on a drug which is taken for its psychological effects

necessarily an abuse of that drug? Few people would, I suppose, quarrel with the view that this is true of morphine, heroin and cocaine, though someone recently wrote to the Press and complained that, since he found it necessary to take heroin, he did not see why his freedom to do so should be interfered with. But there is rather less unanimity about cannabis, and where do alcohol and tobacco stand? (I use the term tobacco here comprehensively to include whatever its pharmacologically potent constituents may be.)

Tobacco and alcohol may both be drugs of dependence. Their action is pharmacological, and in extreme cases the addict attempting to give them up suffers deprivation symptoms, which may be so severe that he is unable to do without them. The fact that they are both drugs which you prescribe and obtain for yourself, instead of through a doctor, and that there are social aspects of their use, is irrelevant to their pharmacological action. As in the case of other drugs of dependence, people vary very greatly in their liability to become addicted, and serious dependence is much more common in the case of tobacco than alcohol. I know of no evidence that tobacco-dependence has any bad psychological effects; but it undoubtedly may have bad physical effects, and it is here that the dependence becomes important, because it may make it extremely difficult for the addict to give up smoking. Alcohol-dependence, in its extreme forms, is recognized to be a manifestation of a psychological illness and calls for treatment accordingly, but as in Britain that cannot be carried out without the willing co-operation of the patient, which is usually difficult to obtain, the serious alcohol addict is a difficult medical and social problem.

I have mentioned both tobacco and alcohol addiction not only because of their intrinsic importance, though that is considerable, but in order to bring out a point of more general relevance. The World Health Organization Committee points out that the characteristic feature of drug-dependence is the strong desire or need to continue taking the drug. Leaving on one side the chronic alcoholic, using that term to describe people whose consumption of alcohol leads to such psychological or physical ill-effects that they are in need of medical treatment there are many others who habitually take alcohol in more moderate amounts and claim that they feel and are the better for it, and miss it, if for some reason they are unable to get it. They would agree with a patient of mine who once said: "Alcohol has been a very good friend to me". This is a point to which shall return.

What are we to think of this steadily rising consumption of barbiturates and tranquillizers? Before we can answer this question, which is a very complex one, we need a great deal of information which is not at present available. As the first Drug Addiction Committee said in its report: "It is clear that there is scope and a need for operation research into the prescribing pattern in this country with particular reference to habit-forming drugs". We need to know first how many patients are receiving prescriptions for barbiturates, and what is the average amount prescribed for these patients per annum. Then we must know what proportion of them are receiving barbiturates for treatment of epilepsy. An epileptic patient on barbiturates is drug-dependent because he cannot give up the drugs without serious ill-effects, but this type of drug-dependence is a use and not an abuse of the drug. Having eliminated those prescriptions, the next thing we need to know is what proportion of the tablets prescribed the patient actually consumes. Doctors, I am sure, would over-estimate their patients' faith in their prescriptions if they supposed that the tablets they prescribe are regularly and faithfully consumed by every patient. So we need to know from an appropriate sample of patients what proportion of the barbiturates prescribed for them they actually take.

and if they do not take them all, what do they do with the rest? This is a question with several practical implications. Are the superfluous tablets locked up, or thrown away, or left about, where perhaps a child can find them? Moreover, if the patient puts them safely away, does he himself know what they are when he turns them out again in a year's time? It has sometimes been suggested that the prescription of excessive amounts of barbiturates by some doctors may be a source of such drugs for the black market. In any event, I think it is clear that prescription figures are likely to be a very misleading guide to actual consumption.

Nevertheless, let us assume—and experience shows that this is a reasonable assumption—that there are patients who are drug-dependent on barbiturates, not in the sense that they are in a state of chronic barbiturate intoxication, but that they are more or less regular consumers of barbiturates, either as hypnotics or as general sedatives to blunt the sense of being stretched on 'the rack of this tough life'. If this is drug-dependence, is it a use or an abuse of the drug? In the passage I quoted from the first report of the Drug Addiction Committee, it will be remembered, occur the words "often, however, a prescription is given for a drug when the patient's real need is a discussion of his psychological difficulties with the doctor". No doubt, this is sometimes true, but we have to remember that the average doctor to-day is much too busy to be able to spare the time for that kind of psychotherapy except on rare occasions, and though it would undoubtedly sometimes be helpful, many people would doubt whether psychotherapy, even if it were available, is the most suitable form of treatment for many such patients. Underlying a critical attitude to the regular prescription of barbiturates or other sedatives for the purpose I have mentioned, I think I can detect a hidden assumption. Let us look for a moment at another instance, namely, the administration of tranquillizers, which amounts to drug-dependence, but is nevertheless universally regarded as a use and not an abuse: I refer to the modern pharmacological treatment of schizophrenia. The regular administration of chlorpromazine and similar drugs to schizophrenics has enabled many of them to leave a mental hospital and live in the community so long as they take the drug regularly. Comparable beneficial results have been achieved by the treatment of patients suffering from depression by the antidepressant drugs. The authors of a recent monograph on the subject summarized the results of these forms of treatment as follows: "In general, these psychopharmacological agents have facilitated the control of mood and behavioural disturbances. In the mental hospital setting, they have induced a more quiet and more orderly atmosphere. They have enabled the discharge of an increasing number of patients and the return of many, previously resistant to treatment, to their appropriate places in society. In addition, they have facilitated ambulatory and out-patient treatment and have lessened the need for shock therapy". Here, then, is a beneficent form of drug-dependence in the case of patients suffering from major psychological disorders. Why, then, or in what circumstances, should we question the use of similar drugs in the doctor's consulting room for the treatment of patients suffering from minor psychological disorders? Is it perhaps because we are inclined to draw a line between gross psychiatric illnesses, for which we feel the patient cannot in any way be held responsible, and which are due to the operation of unknown physical factors, which may turn out to be biochemical, and the minor psychological disorders for which we do not postulate any physical cause but tend to attribute to psychological causes, and to regard as reactions to stresses and strains to which, perhaps we think, the fortunate majority of us are too tough to succumb. We recognize that it is of no use to admonish the schizophrenic as a general rule, but would not many of our neurotic patients, we wonder, be better as a result

of some effort on their own part? This, of course, raises a difficult philosophical question involving the relationship between the mind and the brain. I shall not discuss this further now, but I doubt whether it is philosophically sound to make any such distinction between the major and the minor psychological disorders. We cannot interpret schizophrenia or depression purely in psychological terms, nor, for that matter, can we at present give a physiological explanation for them. It often appears easier to give a psychological explanation of the minor neurotic disorders from which many people suffer; but that does not exclude the probability that they, too, have physiological explanations which we shall one day discover. The mind and body constitute a complex unity, and when we are dealing with psychological disorders, we always need to take account of both psychological and physiological interpretations so far as we can achieve them. It may well be that for the kind of reasons I have already mentioned some patients receive prescriptions for sedatives indiscriminately; but that is a long way from saying their continuing use involves a form of drug-dependence which is an abuse. I quote once more from the report of the first Drug Addiction Committee: "it is not for us to decide whether their occasional or even regular use is justified if it enables a person to lead a happier and more useful life". If you are among those who regard alcohol as a friend, you may also think the same of the regular use of sedatives in suitable cases.

But, in my view, the real limitation to the best possible use of such drugs springs from our ignorance. Let me end by looking into the future. I foresee a day when we shall understand much more than we do now about the relationship between the brain and the mind. On one hand we shall have methods of making accurate psychological assessments of the personality, very possibly in terms of factors which find no place in our present psychological vocabulary. We shall then be able to interpret psychological disorders in terms of these functions, their mutual interplay, and their reactions to our experiences. Parallel with these developments, psychopharmacology will have been placed on a rational instead of an empirical basis. We shall think in terms of the normal biochemistry of nerve cells and synapses, their groupings and interactions, their disorders and the effect of drugs on them. As a result, correlating in this way psychology, physiology, biochemistry and pharmacology, we shall have not only a more comprehensive armamentarium of drugs, but much more precision and individualization in their use. All we shall need then will be enough doctors with time to use them. But it would be wrong to leave the matter there. If mind and body are a unity we must not concentrate on the physical treatment of stress to the exclusion of its psychological aspects. Here, however, we need to look beyond individual psychotherapy and take a broader view. As the first Drug Addiction Committee said in its report, the cause of psychological maladjustment should be sought perhaps as much in social conditions as in the mind of the individual. So far as we know, life has always been stressful, and looking back over history and prehistory, it becomes clear that, although we have our own peculiar stresses, we have eliminated a great many which our ancestors had to put up with. Indeed, stress seems inherent in the evolutionary principle. There will always be some who find life too much for them, and they will continue to need help from pharmacology and supportive psychotherapy. We are all aware of the challenge to international and social organization which some of our major current stresses present. Beyond that, there is still much to be said for the ideal of fighting our own battles if we can without the aid of pharmacy, but with the support of some philosophy which gives a meaning to life, and from which we can draw strength and support.

RESEARCH AND MANAGEMENT IN EAST AFRICAN WILDLIFE

By DR. JOHN MORTON BOYD*

Nature Conservancy, 12 Hope Terrace, Edinburgh

THE problems of management of national parks, game and forest reserves and pastoral lands have much in common, and there is an increasing awareness that many forms of use of land in these fields are wasteful, non-conservative and positively destructive. Almost without exception this applies to the pastoral and game lands of East Africa, involving so vast an area and so wide a range of problems, many of which are political and social as well as scientific, that the mind shirks the idea of reform. The solutions lie in wise management of the land, 'wise' meaning informed by long experience or research. There is thus established a close link between research and management in the planning of large natural areas. The ideal blueprint would appear to be a two-tier organization with a superstructure of management supported by a basement of research. Whether it is possible to achieve such an ideal in the national parks and game reserves of East Africa is doubtful, though it is already well established in forestry, and there is a semblance of such an arrangement in the Queen Elizabeth and Serengeti National Parks.

The Research Effort

The research being brought to bear on management in game, forestry and cattle falls far short of what is required, that on game lagging well behind the others. The national parks and game departments from time to time acquire the services of one or two biologists to undertake specific research projects (not all closely geared to management); with the exception of the very small and inadequate Fauna Research Section of the Kenya Game Department (FRSKGD), none has established a research division likely to cope with the future advisory needs of parks and reserves. The Tanzanian National Parks have set up the Serengeti Research Project (SRP) based on foreign aid; this may later develop into a permanent research division. The East African Common Services Organization (EACSO) provides advice on aspects of forestry and animal husbandry through the East African Agriculture and Forestry Research Organization (EAAFRO) and the East African Veterinary Research Organization (EAVRO); but the proposed Wildlife Research Division of EAAFRO is not yet in being. University departments maintain an independent approach to wildlife research: the work on mammalian ecology being done in the Department of Zoology, University College, Nairobi, includes ecology of the alpine zone of Mount Kenya, ecology of small mammals, biology and ecology of the rock hyrax, behaviour of wild ungulates, feeding habits of wild ungulates, temperature regulation and water balance in wild ungulates. All these investigations can be vaguely related to managerial problems in the national parks and game reserves, yet none is so orientated and will necessarily assist conservation. The Nuffield Unit of Tropical Animal Ecology (NUTAE), based in the Queen Elizabeth Park, is a research consortium between Cambridge and the East African university colleges; the work there concerns populations of large game species and their pastures within the managerial units of the Queen Elizabeth and Murchison Falls Parks.

* Nuffield Travelling Fellow, 1964-65.

Visiting research fellows are normally associated with one of the research institutions and usually their work has managerial overtones.

Terms of Reference

Terms of reference depend to a great extent on the way in which research workers are recruited. For the suitably qualified person the opportunities are almost unlimited, and it is a matter of making the necessary influential contacts and of choosing a project which will win financial support. This has resulted in a great deal of free-lancing by those intent on 'pure' rather than 'applied' work. With the exception of the Canadian biologists with the Uganda Game Department and those concerned with the immobilization techniques for big game, few have come forward to undertake projects in actual wildlife management. This dearth of applied workers probably stems from there being some grant-giving bodies strictly devoted to pure science, from grant-giving committees and the corps of research workers being drawn from the ranks of pure scientists, and from applied projects being usually more difficult to conceive and plan and requiring more money and time than pure ones. The situation has not developed into a 'free-for-all', however, and this has been largely due to the channeling of funds through the research institutes.

The Nuffield Unit of Tropical Animal Ecology, the Serengeti Research Project and the Fauna Research Section of the Kenya Game Department have been established in the field of wildlife research. The NUTAE terms of reference do not provide a linkage between research and management, while SRP and FRSKGD have as yet no terms of reference. Nevertheless, both NUTAE and SRP are situated in national parks, investigating populations of game which are subjects of management. The fact that the NUTAE programme began with the hippopotamus problem in the Queen Elizabeth Park and SRP with the game-migration/park boundary problem in the Serengeti leads one to believe that the intention of both was to assist in the solution of these problems. These research units fall between the stools of applied and pure research, and this has given rise to widely divergent views on what part they should play in providing a research arm to the national parks and game departments. Routines such as game-counts and cropping are, in the early stages of survey, matters of research; later, when the research has been completed, they become matters of management. This shift of routines from 'research' to 'management' has further confused the role of the research units, but clarification has lately been achieved at the Queen Elizabeth Park, where hippopotamus-counting and hippopotamus-cropping have been handed over by NUTAE (as expired research routines) to the park warden and his staff. Nevertheless, although NUTAE and SRP have as yet no planned connexion with management, they have provided advice for the management of the hippopotamus and the drawing of boundaries, respectively.

A trend is noticeable which may destroy the developing two-tier organization; this is the raising of investigations

from the simple to the complex, transforming what was originally immediately useful applied research into longer-term pure research. The irresistible desire of the research worker to probe deeper and deeper into his problem is the driving force to scientific progress and should not be blighted; but care must be taken that it does not violate the terms of reference of applied research. If no terms of reference are available, this trend to fundamentalism will go unchecked and research may become progressively detached from its managerial context; the terms of NUTAE are formulated to permit such trends in present research. The raising of what were originally ecological investigations of vegetation and game in fairly simple quantitative and qualitative terms to investigations of primary and secondary biological productivity could be one such trend. Measurements of this complex quantum may come to influence use of land in the long term; but in the meantime the pressing problems of the present and nearer future require to be tackled on simpler lines.

A much greater volume of applied research must be carried out with precise terms of reference stating clearly the limits to which the work can be taken and emphasizing that its object is application to wildlife management.

Impact of Research on Management

Park and game wardens often state that their managerial problems require research. This may be true; but it is questionable if the scientist can, in fact, provide the answers to them. The hippopotamus-cropping in Queen Elizabeth Park is an example of the scientist providing the answers. How far have these been applicable? In a classical study, R. M. Laws has described the population of hippopotami inhabiting the Queen Elizabeth Park, stating its size, spatial distribution, age structure, social structure, behaviour, reproductive rate and so on. Logically there should follow a detailed plan for the culling of the population showing the proportions of each sex and each age-group of each sex which should be taken. Yet there is little use of going to all this trouble, for the practical difficulties faced by management staff in recognizing the sexes and age groups in the water are almost insuperable. What, in fact, is resulting from this detailed investigation is a non-selective shooting of large hippopotami as they come into the sights of the park warden's rifle, with conservative culling levels set by the total numbers occupying the cropping sites. The links between this pure research and management of hippopotami are strong; but the managerial profit from it is disproportionately small. The same can be said for the plans produced from the cropping of elephant in the Tsavo Park in Kenya. Aerial counts of the elephant population were followed by J. Glover's statistical analysis of population size, age classes and class trends and schedule for the progressive reduction of numbers over ten years with minimum killing and damage to herd structure; but implementation proved unworkable.

Very often the rate of change of many of the forest and game habitats of East Africa outpaces the conservation machine set up to cope with it. One need only see the regrowth of the woody vegetation in the Ankole/Masaka Ranching Scheme, or the devastation by elephants to the savanna woodlands in the Tsavo Park, to appreciate this. Ecological research is a slow process more able to cope with relatively slow changes such as those caused by climatic variation, burning of vegetation or abstraction of water, the effects of which usually occur gradually over many years. Technical research in the wildlife field, on the other hand, can make rapid advances; for example, the development of capture techniques for large game, the prediction of live-weight of game animals from the weight of the dissected back leg, the elimination of the

tsetse fly, *Glossina morsitans*, with dieldrin and so on. But most of the management problems in East Africa are not simply scientific, they usually have political implications.

The findings of applied research take time to reach the ground for which they are intended. As they affect East African wildlife they require to be considered against a background of a sluggish system of consultations with senior advisers, usually from Europe or the United States, and committees in which financial and political considerations are dominant. Thus the impact of the research becomes progressively eroded: seldom can clear-cut scientific recommendations be applied, and the scale to which they are disregarded is of great importance to the morale of research workers. The resettlement scheme in the Serengeti provides an excellent example of a game-management problem in which the adjustment of boundary ecology is recommended as a result of applied research. The problem is, however, also a complex political and social one, and it remains to be seen whether the *raison d'être* of the research is not lost in political compromise between the interests of the Serengeti National Park and those of the neighbouring people.

To sum up, the impact which wildlife research in East Africa has on the management of the national parks and game reserves is greatly reduced by the following main factors: (1) much of the ecological research is 'pure', with no direct application to management; (2) research which started as 'applied' may later become more fundamental and 'pure'; (3) the recommendations which follow research may be impracticable on the ground; (4) the recommendations which follow research may be nullified by political and financial factors; (5) the recommendations of research are dealt with by inefficient consultative machinery.

Despite all this, there is no doubt that the scientist can make a significant contribution to the management of the wild habitats of East Africa. The great volume of inventory work on the flora and fauna, in which P. J. Greenway's on the flora is outstanding, and basic surveys such as H. F. Lamprey's on the ecological separation of game species, have laid a sure foundation. Nevertheless, positive conservation needs more than simple cataloguing; it needs ecological knowledge, insight and action. Despite the difficulties of research in organizing itself, making itself practically acceptable and making its voice heard in the political winds, the scientist has a major part to play. At present conservation is in the hands of the wardens, only one of whom, to my knowledge, has a university training in science. These men are driving their conservation very hard and calling for scientific advice which is seldom forthcoming. The warden has a major part to play, and few scientists could take the place of D. L. W. Sheldrick in his knowledgeable and intuitive handling of Tsavo (East); nevertheless, scientists are needed also. The complementary roles of scientist and warden are seen with E. M. Watson and M. I. M. Turner in the Serengeti, and it is salutary to think that this is the only fluent combination of research and management to be at present encountered in the national parks and game reserves.

Roles of Research Institutes

The existing research institutes dealing with wildlife and forestry in East Africa are the Government departments (including the national parks), EACSO and the university colleges (including NUTAE). All these are constituted differently and have a different attitude to research.

The game departments and the national parks are aiming at the conservation of the game habitat in perpetuity. This is a vast undertaking, involving management and research in water, soils, grasslands, forests, insects and game. The management side is already in

being in both, but as yet there is little development on the research side. SRP, FRSKGD and the two Canadian biologists with the Uganda Game Department are perhaps buds from which research divisions could grow, but they are not permanently engrafted and none is showing signs of growth.

The research divisions of national parks and game departments should be concerned almost entirely with applied research. Their primary aim should be the maintenance of the scientific record of the game lands by standard physical and biological measurements which will show ecological change. This would, in time, mean the establishment of a registry of scientific data and archives. The secondary aims of such a research division would be the establishment of permanent scientific staff to carry on very long-term projects of up to fifty years or more in the drawing-up of life-tables of the elephant, hippopotamus and other long-lived game and examining the vegetation and game successions. The scientific registry and archives would be available to short-term workers, a few of whom might work in the research division, but most of whom would be accommodated in the university colleges and elsewhere. Such research divisions can only be permanently established if the respective Governments make funds available; this has already been done with FRSKGD, but more is needed if the new divisions are to grow. The whole future of national park and game resources in East Africa may depend on such funds being made available immediately.

SRP is a national parks research unit in which a determined attempt is being made to bring inter-disciplinary research to bear on the management of the Serengeti. It has the makings of a research division to the Tanzanian National Parks, but is at present financed entirely from foreign sources and lacks permanency. Funds are provided by UNTAB, FAO, the Fritz Thyssen Stiftung, the Netherlands Foundations for Pure Research, the German Government, the Nuffield Foundation and the Deutsche Forschungsgemeinschaft. SRP work is likely to continue for some years as a group of related short-term projects of up to five years duration. There is no indication so far that really long-term work will be possible.

The research undertaken by the long-awaited Wildlife Research Division of EAAFRO will abide by the broad terms of reference of EACSO to provide research which has equal valency in Uganda, Kenya and Tanzania. It will follow the pattern of the work already in progress in forestry, agriculture and veterinary investigations. In a paper to the Wildlife Research Co-ordinating Committee (which has recently been reconvened after a year of inaction), E. W. Russell gives an outline of the functions of the Division. There would be two permanent scientists: the senior would maintain a bureau of East African wildlife research and act as a senior consultant and adviser; the junior would carry out specific research projects under the general direction of the senior, who would be head of Division. Short-term grant-aided workers might join the Division from time to time.

The research potential of the university colleges is provided by a few members of staff and postgraduate students working for M.Sc. or Ph.D. degrees. At University College, Nairobi, Prof. D. S. Kettle is giving emphasis to wildlife research in the constitution of his postgraduate school. As already stated, the choice of studies, however, is independent of the needs of management, and it is right that this independence be maintained by the universities. African wildlife is bristling with research opportunities in classical zoology (including ecology), and the university departments must not become too tied to wildlife management but be absolutely free to exploit these. The universities are therefore capable of providing short-term workers, mostly dealing with narrow, clear-cut studies in 'pure' science.

NUTAE is a university research unit; but its approach to research is coloured by its being based in the Queen Elizabeth National Park. It retains its independence from the Uganda National Parks, and although it is working in close contact with some of the important management problems both at the Queen Elizabeth and at Murchison Falls, it cannot in its present form be looked on as the beginnings of a research division of the Uganda Parks. NUTAE is endowed by both the Nuffield and the Ford Foundations and is linked with the International Biological Programme (IBP); workers are attached to the University of Cambridge, Makerere College and University College, Nairobi. The Unit is run by a committee headed by Prof. C. F. A. Pantin. Its work is likely to be pure research (some of which will be closely linked to management) and usually in short-term projects of up to five years.

The Uganda Forest Department has a thriving research division, and those who are planning the future of the national parks and game departments should note how this has been achieved. The silvicultural research in softwoods gives quick and simple answers to pressing questions on which depend the country's future timber resources. In hardwood silviculture, however, the task of finding the best methods of regenerating a high forest of desirable trees from the tattered remnants left after exploitation and refinement is a huge and complex one yielding slow results. Yet this is applied research with the stability and endurance which are needed in game management; some of the experimental plots in the Budongo Forest were established in the mid-1930's and are still yielding information. The division of effort in research between the forest departments and EAAFRO is also worth noting when coming to consider the relations between the Wildlife Division of EAAFRO and the national parks and game departments. The work of EAAFRO in forest genetics and pathology is more fundamental than the silviculture of the departments, and this sharing of load is a good working arrangement.

The existing research institutes cater almost entirely for short-term research, the span of which is set by a grant or by the number of years workers remain in university posts. EACSO may be an exception, but its Wildlife Division is not yet in existence. Nothing has yet been provided for long-term research with workers appointed to specific projects lasting twenty years or more. None of the present institutes can offer any opportunity for this; only Government departments and perhaps EACSO can provide the stability in finance and organization necessary to maintain such a long-term research facility; it has already been done in forestry.

The need is for properly constituted (joint) research divisions in the national parks and game departments of each territory, with a co-ordinating council in EACSO.

Conclusion

In his paper, "A Survey of the Past and Present Wildlife Research in East Africa", L. M. Talbot has shown what a vast effort has been invested by the 114 workers cited and the depth of their work as described in some 220 papers. Yet how much of this effort has contributed to the wise management of the East African game lands? I would venture to say very little, though the culling of hippopotamus and elephant in the Uganda Parks is a notable exception. The foggy terms of reference which research has to management, the lack of impact which research has on the course of events, and the lack of planning of long-term research and management cannot be allowed to continue while the wildlife resources are diminishing before our eyes. There can be no alternative to constructive management/research planning backed by efficient co-ordinating machinery for every national park and game reserve, just as there has already been for most forest reserves.

OBITUARIES

Sir Ian Richmond

I. A. RICHMOND, professor of the Archaeology of the Roman Empire in the University of Oxford, died on October 4 at the age of sixty-three. He was educated at Ruthin School and Corpus Christi College, Oxford. Studentships from his university and the British School at Rome enabled him to engage for two years after graduation in field research centred on Rome. In 1926 he was appointed lecturer in classical archaeology and ancient history at Queen's University, Belfast, whence he returned to Rome as director of the School. In 1935 he was appointed to a post in Roman-British history and archaeology in the Newcastle upon Tyne Division of the University of Durham, where he remained, as lecturer, as reader and as professor, until 1956, when he accepted the post in Oxford which he held until his death. He received a knighthood in 1964, the same year as he became president of the Society of Antiquaries of London.

Richmond had few equals either in investigation or in exposition. Almost all aspects of Roman provincial archaeology have been enriched or illumined by his activity, and he has been justly acknowledged for several years as the leading authority in a by no means narrow field.

The twin son of a Lancashire surgeon, Richmond sometimes compared his own work as an excavator with that of a surgeon. He had a flair for, and much experience in, the study of structural evidence. This enabled him to be economically selective in an excavation and still to obtain the full picture, as he did that of the legionary fortress at Inchtuthil in Perthshire, a little at a time over fourteen years. The method was only successful in his own hands, for less skilled excavators require a bolder approach. Richmond would excavate boldly when occasion demanded, and strip off a whole site level by level. Excavators the world over have benefited from working with him on the Corbridge training courses, where he taught techniques by example rather than precept.

On Hadrian's Wall, Richmond provided the sustained effort which brought to fruition programmes of research sometimes initiated by others and carried through in collaboration. In the decade before and the years immediately after the Second World War, problems which had remained obdurate for generations were tackled in a scientific spirit and solved finally and convincingly. The Museum of Antiquities in Newcastle upon Tyne, which he opened in 1960, was largely his creation, and is a permanent monument to him.

Richmond was a first-class teacher, but never surrounded himself with a large circle of undergraduates or recent graduates; for good or ill that was not his way. He was given honorary degrees by six universities, including that where he had spent half his working life. Learned societies and universities also honoured him by asking him to deliver endowed and named lectures. He will be remembered by a wider public for the hundreds of lectures, illustrated, delivered without a script out of the depth of his knowledge, sound, clear and gravely gay, which he gave, up and down the country, to any interested audience.

He held the highest office in national societies, and was a valued member of national boards and commissions in both England and Scotland; he also found time, when already a busy man, to hold office in local societies and to serve on committees and councils. He was no passenger on these bodies, and his cheerful common sense was much in demand. He used the time on the long train journeys to draft his reports.

Richmond's published work includes *The City Wall of Imperial Rome* (1930), a substantial contribution to the

Northumberland County History—*The Romans in Redesdale* (1940), the tenth (1947) and eleventh (1957) editions of the *Handbook to the Roman Wall, Roman Britain* (Collins, 1947), *Roman Britain* (Pelican, 1955); and *Roman and Native in North Britain* (1958). Excavation reports, illustrated by his own photographs and drawings, and substantial papers on many different facets of his main subject, are to be found in the journals of local and national societies.

He was not merely an able man, but a good man. He took an unconcealed delight in success, but was never ambitious at the expense of others. He would spend hours with the writer of a paper or report going through it with him sentence by sentence improving the language. On meeting an acquaintance he never failed to ask the right question about himself and his family. He could be stern, but was always open; his normal mood was of robust good humour and impish wit. He would help a friend or colleague when he needed it most and seemed to deserve it least. It was his explicit policy to do things for other people; he did so as if he were indefatigable, which unfortunately he was not. J. P. GILLAM

K. R. Butlin

KENNETH RUPERT BUTLIN died on October 1, 1965, at the age of sixty-eight. He was educated at Oundle School and, with an interruption for military service, at Trinity College, Cambridge. Shortly after the First World War he took a first in chemistry and almost immediately left for Argentina, where he worked on the fermentation of sugar. Thereafter he remained interested in the chemical activities of micro-organisms and, returning to the United Kingdom in 1929, he joined A. C. Thaysen's group of microbiologists, then working at the Royal Naval cordite factory at Holton Heath. This group was transferred as a unit to the Chemical Research Laboratory, Teddington, in 1933, and it was from Teddington that Butlin published the research for which he will be most remembered.

His earliest papers were concerned with the chemical activities of the acetic acid bacteria, and his review of these organisms is still required reading for those interested in the subject. During the Second World War, Butlin, with the rest of Thaysen's group, turned his attention to the problem of food yeast production, making use of molasses, a project which gave him valuable experience of large-scale production of microbes and which involved, incidentally, one of the earliest uses of continuous culture. At the end of the War, Thaysen and H. J. Bunker (a leading authority on the sulphur bacteria) left Teddington, and research on microbiology at the Chemical Research Laboratory was left in the hands of a small section of the Corrosion Group, headed by Butlin, studying bacterial corrosion. This process is largely the responsibility of the sulphate-reducing bacteria (*Desulfovibrio*), and Butlin's small group rapidly established themselves as leading authorities in this field: they were, for example, among the first to work with authentically pure bacterial cultures.

The then director of the Chemical Research Laboratory, R. P. (now Sir Patrick) Linstead, perceiving the broader ramification of chemical microbiology, initiated the expansion of Butlin's microbiology section until, in the early 1950's, it became an independent Microbiology Group, mainly concerned with the study of sulphate-reducing bacteria but also with a variety of bacteria of economic and industrial importance. In 1950, Butlin accepted responsibility for a few hundred bacterial cultures of industrial importance which the National Collection of Type Cultures proposed to discard, and thus

founded the National Collection of Industrial Bacteria, now located at the Torry Research Station, Aberdeen. The 1950's were the most productive period of Butlin's career: his Group worked on such strictly practical topics as the feasibility of producing sulphur on an industrial scale with the aid of bacteria, control of pollution in waterlogged gravel and clay pits, bacterial leaching of ores, bacterial contamination of petroleum; topics of less-direct applicability such as the mechanism of microbial oxidation of phenols (important in biological effluent treatment) and the continuous culture of anaerobes; relatively academic matters, though still having a practical background, such as the biochemistry of sulphate-reducing bacteria and the mechanism of the methane fermentation. By 1958, Butlin's Group was the major British research unit concerned with basic economic microbiology. The blow to British research, resulting from its disbandment by the Research Council of the Department of Scientific and Industrial Research, reverberated throughout the scientific world; it still evokes strong opinions among microbiologists, both here and abroad. Having staunchly resisted the disbandment of his Group, Butlin was compulsorily retired from the Scientific Civil Service in 1959, but, undismayed, he often emerged from retirement to undertake consultant work or to attend scientific meetings.

Butlin's conviction that microbes are of the greatest potential importance to industry, not only in production but also in the deterioration or disposal of industrial products, was fundamental both to his work and his scientific reputation. He was also a man of striking personality and culture. He was a great lover of opera; he enjoyed travel, good food, wine and companionship; he was firmly literate in the sense that he believed that, if work was worth writing up, it was worth writing well. The literary standard of his publications and, perforce, those of his Group, was high. But, most of all, he had an enormous capacity to enjoy life, an ability which he never failed to communicate to his companions, so that even quite solemn or troublesome occasions took on the character of a party or a convivial gathering. His personality inspired strong affection and he will be sadly missed, not only by his intimate friends, but by innumerable acquaintances and scientific colleagues all over the world on whom his sunny and friendly disposition made an unforgettable impact. His wife, *née* Helen Mary Fletcher, survives him; their son, Martin, is an assistant keeper at the Tate Gallery.

J. R. POSTGATE

Prof. H. Schardin

PROF. HUBERT SCHARDIN, ministerial director, Ministry of Defence, Bonn, honorary director of the Franco-German Research Institute at Saint-Louis, and director of the Ernst Mach Institute at Freiburg-im-Breisgau and Weil-am-Rhein, died on September 27, aged sixty-three.

Prof. Schardin was a good scientist and a fine man who inspired many to both scientific effort and to international understanding. The situations already mentioned do not include the capacities by which I best knew him. He was the German delegate to the International Congress on High Speed Photography, European pivot of this subject, one of the very few present at all such congresses so far and to many a legend in his own lifetime.

His whole career had been devoted to, first, ballistics, leading naturally to high-speed photography—Schlieren investigations in particular—and to philosophic interest in time. He joined Cranz in Berlin in the mid-1920's—and their association will always be remembered for their multiple spark, multiple camera technique of 1928 known simply as the Cranz-Schardin system and used in every laboratory which investigates projectiles in their many guises.

Cranz provides the link from to-day back to the scientific era of the nineteenth century and such names as Toepler and Mach, just as Schardin is a strong link to the earlier decades of this century.

When Cranz retired in 1935, Schardin took over as the German leader in ballistic photography and was in charge of the Ballistic Institute of the Technical Academy of the German Air Force from then until 1945. Later, the Franco-German Research Institute at Saint-Louis was founded with Schardin as its director. The works of this Institute, its director and his colleagues speak for themselves.

Prof. Schardin will be missed and remembered affectionately by many people in many countries, and especially by those interested in the same disciplines and philosophies. The British National Committee for High Speed Photography believes that a prize in his honour should be presented at International Congresses on High Speed Photography for worthy contributions to the subject. It could be known simply as the "Schardin Award", and the British Committee would be pleased to support such a commemoration.

G. H. LUNN

NEWS and VIEWS

The Royal Society of London : Award of Royal Medals

HER MAJESTY THE QUEEN has been graciously pleased to approve recommendations made by the Council of the Royal Society for the award of the three Royal Medals for the present year as follows: to Dr. R. A. Lyttleton, reader in theoretical astronomy in the University of Cambridge (presently at the Institute of Astrophysics, Brandeis University, Waltham, Massachusetts, U.S.A.), for his distinguished contributions to astronomy, particularly for his work on the dynamical stability of galaxies; to Dr. J. C. Kendrew, deputy chairman of the Medical Research Council Laboratory of Molecular Biology, Cambridge, for his distinguished contributions to the complete structural analysis of a protein molecule (myoglobin), particularly the biological aspects of this study; to Dr. H. C. Husband, chartered civil engineer (of Messrs. H. C. Husband and Co., Sheffield), for his distinguished work in many aspects of engineering, particularly for his design studies of large structures such as

those exemplified in the radio telescopes at Jodrell Bank and Goonhilly Downs.

Mathematics in the University of Edinburgh :

Prof. A. C. Aitken, F.R.S.

PROF. A. C. AITKEN has retired from the chair of mathematics in the University of Edinburgh, where he has been a lecturer and reader from 1925, and where he succeeded Sir Edmund Whittaker as professor in 1946. Born and educated in New Zealand, Aitken went to Edinburgh in 1923 at the age of twenty-eight as a research student, accompanied by his wife. There he received in 1925, not the degree of Ph.D. for which he was registered, but that of D.Sc., for a thesis recognized as being of quite outstanding originality and merit. No doubt his phenomenal powers of mental arithmetic provided the original impetus which led him, both in this thesis and later in many published papers, to devote so much of his life work to practical mathematics and numerical analysis. He has

also undertaken substantial and wide-ranging work in two other fields, namely, mathematical statistics and the theory of matrices and determinants. He collaborated with H. W. Turnbull in a text-book which has become a classic, *The Theory of Canonical Matrices* (1932). From 1939, together with D. E. Rutherford, he edited the series of University Mathematical Texts published by Oliver and Boyd, himself contributing the first two volumes. Between 1925 and 1962 he published some 70 mathematical papers, while his brilliancy as a lecturer inspired many generations of undergraduates and research students and his colleagues, with whom also he shared his profound knowledge of classical and modern literature and of music. Before coming to Britain, Aitken served with the New Zealand Expeditionary Force from 1915 until wounded in 1916. His experiences during the First World War were described with vivid realism in a manuscript drafted in 1917, which was rewritten and published in his book, *Gallipoli to the Somme* (1963).

Prof. Aitken has been succeeded jointly by Prof. A. Erdélyi and Prof. F. F. Bonsall (*Nature*, 208, 19; 1965).

Physics in the University of Sussex :

Prof. M. W. Thompson

DR. M. W. THOMPSON, who has been appointed to a chair in physics in the University of Sussex, was educated at Rydal School, Denbighshire, and at the University of Liverpool, graduating with first-class honours in physics in 1953. In 1963 he was elected to fellowship of the Institute of Physics and in 1964 was awarded a D.Sc. by the University of Liverpool. In 1953 he joined the Atomic Energy Research Establishment, Harwell, at first in the Reactor Physics Division and later in the Metallurgy Division, where he has been in charge of the Radiation Damage Processes Group from 1960 onwards. The first problems he worked on were the neutron economy of nuclear reactors and techniques for neutron detection. In 1954 he turned his attention to radiation damage in metals. By carrying out irradiations in a reactor at very low temperatures he was able to identify the temperature ranges in which point defects become mobile in the refractory metals. This work led to an interest in atomic collision processes in crystals, which are responsible for both radiation damage and sputtering; and, in a series of sputtering experiments, he was able to prove the existence of focused collision sequences and to study their characteristics. In pursuing his interest in the interaction of ion beams with crystals, he produced some of the first evidence for the channelling of ions through crystals. More recently, he has shown that, on account of channelling, nuclear reaction rates depend on crystal orientation; and, on the basis of the channelling phenomenon, he is at present developing a technique for investigating crystals and their defects.

Genetics in the University of Aberdeen :

Prof. H. J. Evans

THE University of Aberdeen has announced the appointment of Dr. H. J. Evans to a newly created chair of genetics. Dr. Evans has rapidly and deservedly earned an international reputation as a cell biologist. This stems from his work during the past ten years at the Medical Research Council Radiobiological Research Unit. Born in Llanelli nearly thirty-five years ago, he won a State scholarship to the University College of Wales, Aberystwyth, where he graduated B.Sc. in 1952 and went on to gain a Ph.D. for his work in genetics in the Department of Agricultural Botany under Prof. P. T. Thomas. From Aberystwyth and the cytogenetic study of mushrooms, Dr. Evans made the successful transition in 1955 to radiobiology at Harwell under Dr. G. J. Neary. The combination of physicist and cytogeneticist proved extremely fruitful, as witnessed by a series of much quoted joint investigations in mitotic delay, oxygen and other

environmental effects, relative biological effectiveness for various radiations including fast neutrons and ultra-soft X-rays. In 1960 Dr. Evans, after a profitable year at Brookhaven National Laboratory in Long Island, New York, adroitly escaped the blandishments of the brain drain. He returned to Harwell to continue the profitable association with his biophysical colleagues and to initiate work on radiomimetic agents, DNA synthesis and chromosomal breakage and repair. Within the past year he has led the newly formed Cell-Biology Group and increasingly utilized mammalian and human cells for his work. With his lively and engaging manner, Evans is much sought after as a speaker at scientific meetings in Britain and overseas. He is an active member of many societies and the secretary of the Association for Radiation Research.

British Hovercraft

IN a written answer in the House of Commons on November 11, the Minister of Technology, Mr. F. Cousins, stated that the development of the hovercraft had now reached an advanced stage. During the past year, undertakings both in the United Kingdom and abroad had been operating small hovercraft carrying up to 38 passengers on regular services, and in particular, more than 100,000 passengers had been carried across the Solent in little more than three months. The convenience and saving of time had led to the hovercraft becoming the preferred method of travel for many businessmen on this route. Licences had been acquired by American and Japanese companies to manufacture hovercraft to British designs and patents, and other countries were starting developments of their own. Britain had by far the greatest experience of design, manufacture and operation of hovercraft, and Mr. Cousins believed we still had a lead, thanks largely to the ingenuity and determination of the inventor and the faith shown by the National Research Development Corporation and the manufacturers and transport operators who had taken a stake in this field. A major step forward was being taken with the production of the 150-ton SRN4—four times the size of the largest hovercraft so far built. A Swedish consortium had ordered two SRN4 for a cross-Channel service and the Minister of Transport had approved the proposal of the Railways Board to negotiate for the first SRN4 to operate as a combined car and passenger ferry across the Solent, starting in 1968. Meanwhile, about 25 smaller passenger-carrying hovercraft had been delivered or were on order, and a new light-weight and relatively cheap craft would shortly be put into production. The Government intended to do everything it could to ensure the continuance of Britain's present pre-eminence, and to promote the growth of the industry and the development of exports.

East Midlands Regional Office of the Ministry of Technology

AN East Midlands regional office of the Ministry of Technology has been opened at Cranbrook House, 47 Cranbrook Street, Nottingham. Mr. J. K. L. Thompson has been appointed the senior regional officer in charge of the office, and will have four qualified technologists on his staff. Mr. Thompson has been a member of the Atomic Energy Authority at Aldermaston, specializing in explosive hydrodynamics, although for the past year he has been seconded to the Ministry of Defence. The regional office will help industry to make the best use of advanced technology, particularly by providing information of the latest technical developments, and will also collect information with the view of guiding the Ministry in planning future technical support. It will co-ordinate the work of industrial liaison officers and will co-operate with other Government departments in the Regional Planning Board of the Department of Economic Affairs. Another aspect of the work of the regional office will be

to strengthen the links between industry and the National Research Development Corporation, Government research establishments and those of the United Kingdom Atomic Energy Authority. Three existing regional offices at Cardiff, Edinburgh and Newcastle upon Tyne were taken over from the Department of Scientific and Industrial Research on April 1, 1965, by the Ministry of Technology. Other new offices are sited at Birmingham, Bristol, Leeds and Manchester.

Research and Economic Growth in Belgium

UNDER the title *Research and Economic Growth*, the National Council for Scientific Policy, Brussels, has issued a report on some aspects of industrial research in relation to economic growth, more especially dealing with scientific research and development in the metal industries (*Recherche et Croissance Économique: Rapport sur Certains Aspects de la Recherche Industrielle dans ses Relations avec la Croissance Économique*. Pp. 218. Bruxelles: Conseil National de la Politique Scientifique, 1965). The report is in two parts, each consisting of two chapters. The first chapter surveys the lines of development and demand in European and world trade, with particular reference to the metal industries in Europe and Belgium. The second chapter compares the scale and distribution of research in Belgium and in other countries. The third chapter, which opens the second part, and is based on an enquiry conducted by the University of Louvain, reviews the conditions of technical innovation in the metal industries of Belgium, while the fourth chapter, based on a study made by the Department of Applied Economics, University of Brussels, attempts to assess the development of demand for European metal manufacturers. The report concludes that a structural evolution of the Belgian economy is necessary, particularly in the way of diversification, and new, highly technical activities are most likely to succeed if they start from the strong points of the old technology. The comparatively low level of research in Belgium is attributed to the dominance of industries making intermediate products, and, in the metal industries, of sub-sectors with weak or old technology. The small size of Belgian firms, the majority of which employ and are likely to continue to employ only 100–500 persons, is another hindrance, and policy should be directed to stimulating research in the medium-sized firms. Progress depends on the stimulation of creativity and precedes growth, and the attitude of directors is a fundamental factor in determining the intensity of research. Firms need to become increasingly conscious of the importance of being receptive to change.

Industrial Research and Development in France

Le Progrès Scientifique, July–August, 1965, Nos. 86–87, issued by the General Delegation for Scientific and Technical Research, Paris, contains a survey of research and development in French industry, together with an analysis of the output of qualified engineers in 1964. In 1963 a total staff of 77,000 were engaged in research and development, of whom 16,700 were research workers or technologists, 31,700 technicians and 8,500 administrators. Expenditure is estimated at 3,080 million francs, the total national expenditure on research and development being estimated at 6,215 million francs. This effort is heavily concentrated in the Paris region (70.8 per cent), the Rhône-Alps region (9.44 per cent), the Marseilles region (4.4 per cent) and the Toulouse region (2.9 per cent). Of the personnel, 20.3 per cent are in aeronautics, 19.15 per cent in electronics, 11.3 per cent in the chemical industry, 6.3 per cent in the power industries, 6.25 per cent in electrical construction, 6.1 per cent in precision instrument industries, and 5.6 per cent in the pharmaceutical industry. Comparisons with the industrial effort of the United States are given in some detail.

The National Trust

THE seventeenth annual report of the National Trust for the year 1964–65 records the resignation of the Earl of Crawford and Balcarres, its chairman since 1945. In that period the membership of the Trust has grown from less than 8,000 to more than 155,000. The Trust now owns or protects more than 400,000 acres of land, and 189 historic buildings and gardens, compared with 112,000 acres and 95 buildings in 1945. Of its senior staff of 49, 30 work outside London; but the report emphasizes the need for a further increase in income and membership, which should reach at least 250,000. It is emphasized that there is full co-operation between the National Trust and the Nature Conservancy, and it is pointed out that the Trust now only accepts nature reserves if they are also places of 'outstanding natural beauty', or if it is thought that the Trust has special qualifications to protect the property concerned. Although the Trust owns some nature reserves of the highest quality and importance, its greatest contribution to the preservation of Nature is the fact that it protects all its properties against harmful development. Of the Coastal Preservation Campaign launched in May 1965, the report records that at the end of July, £461,000 had been given (or promised) to the appeal fund, and more than 200 acres at Llochtyn, Cardiganshire, had already been purchased. 31 acres of foreshore at Kearney in Northern Ireland, with covenants over a further 284 acres, and a stretch of more than 650 acres at Whiteford Burrows, in the Gower Peninsula, are being acquired. The Council's objection to the Manchester Corporation's proposals to take more water from the Lake District is also recorded, as well as the acquisition by the Trust of the freehold of the Stratford on Avon canal. An appeal for funds for improvement and maintenance of the canal is included with the report, which concludes with a moving appeal for wider and fuller support for the work of the Trust generally, taken from a speech by Sir Kenneth Clark, at a meeting in the Royal Festival Hall, in March.

Reconditioning Concrete Surfacing

A CASE has recently been reported in the United States of a large municipal car-park in which, following a severe winter in 1963–64, the concrete surfacing deteriorated badly, after only two years of service. "The four-inch layer of concrete on the upper level of the prestressed concrete structure had pitted and scaled, resulting in cracks, rough spots, and holes—some of them down to the reinforcing bars. The pavement was so rough in a number of places that women in high-heeled shoes found walking on it a risky proposition." This happened at a parking garage in Waterbury, Connecticut, and it was due to the repeated freezing and thawing of moisture which had penetrated the surface of the concrete, causing crumbling and pitting, these failures being aggravated by the tyre-chains used on the cars and by de-icing salt reactions on the surfacing, to be anticipated during a severe winter. The same thing has happened, of course, in similar circumstances in some concrete surfacings in Britain and elsewhere. What is of particular interest in the Waterbury example, however, is the method of reconditioning of this deteriorated pavement which, in some respects, is both novel and exemplary; it is certainly not without possibilities in its application, under similar conditions, to comparable problems in Britain and elsewhere. Picking up and repaving bad concrete surfacing with new is both a time-consuming and costly job, often involving many weeks, even months. In the case under review, time was paramount. The quick remedy lay in repairing the damaged surface by application of a cement mortar modified with a specific acrylic bonding agent. According to an article published in *Rohm and Haas Reporter* (Rohm and Haas, Philadelphia (Lennig Chemicals, Ltd., London, W.C.1), 23, No. 4; July–August 1965), procedure was as follows: the surface was scarified to remove loose and

scaling concrete; grease, oil, dirt and salt residue were cleaned off and cracks were filled with a sealant. After wetting with water, the 30,000 ft.² of the damaged surface was treated with a liquid acrylic mortar modifier ('Sonocrete') to "... assure a durable bond between the existing substrate and the fresh mortar subsequently applied". This was followed by a 0.25-in. layer of concrete mortar modified with 'Sonocrete'. The new surface was then swept with a stiff broom to create a serrated finish. After three days, a final coat of 'Sonocrete' was applied to afford additional protection from water and salt. Following a further winter of use, the pavement is still in excellent condition; adhesion to the old surface is described as outstanding; little damage has resulted from freeze-thaw cycles and the abrasion-resistant surface has withstood the punishing effect of tyre-chains and snow-removal plant. This article gives details of other 'Sonneborn' products for use with concrete and masonry, for example, sealants, caulking agents, waterproofing compounds, and decorative protective finishes; also described is a series of 'Rhoplex' acrylic emulsions manufactured by Rohm and Haas which, among other compounds, includes polymers developed specifically for use in modifying Portland cement.

New Zealand State Highways

THE Road Research Unit of the National Roads Board, New Zealand State Highways, publishes quarterly a *Newsletter* which is intended to portray a cross-section of the factors relating to New Zealand road and traffic research problems. In publicizing the activities of the Road Research Unit, this *Newsletter* is also designed to arouse interest and stimulate thinking about road problems, and to indicate periodically the tremendous and ever-growing fund of knowledge of road technology already available. A recent issue of this publication well illustrates its scope (*Road Research Unit Newsletter*, No. 8. Pp. 21. National Roads Board, Wellington, July 1965). The State Highways authorities attach great importance to traffic-volume records on their network of roads, especially for connecting links between towns and rural highways. Automatic counters are used for this purpose to record traffic flows at count stations at country-wide locations. At three-yearly intervals a complete analysis is made to establish the annual average daily traffic values, and a map of both North and South Islands produced to indicate the general form of traffic volumes; one such map, of a part of North Island prepared in 1964, is reproduced in this *Newsletter*; it is most instructive. Another feature is a summary of local road trials and research in progress throughout the country so that all interested parties may be kept up to date with the knowledge of 'who's doing what'; this is to encourage people with particular problems to consult others faced with a similar problem. Fifty-four separate activities are listed, under headings which include topic and scope (nature of the trials, problems involved, materials concerned); location; responsible authority; and state of the investigation to date. An article entitled "Why Full-Scale Road Tests?" lucidly explains, even to the uninitiated, the reasons underlying the practical use and value of trials of traffic-pavement relationship in aiding design of new road foundations and surfacings built to withstand the ever-increasing demands of traffic densities, vehicle speeds and wheel loads, particularly significant in the case of heavy commercial transport, as the Road Research Laboratory in Britain has emphasized for many years past, some of its work in this connexion being quoted in this issue of the *Newsletter*. This is a brief but admirable publication.

Australian Prehistory

In recent years, the prehistory of the southern part of Australia has been set on a firm basis. This is, in large measure, due to the influence of F. D. McCarthy, of the

Australian Museum at Sydney. Nowadays it is no longer a matter merely of collecting surface finds of stone tools and of vague descriptions of the painted rock-shelters, but sites are carefully located and excavated—care being taken to determine the stratigraphy, and to make complete lists of all the various types of tool found. Such an account appears in the June 5, 1964, issue of the *Records of the Australian Museum*, written by McCarthy himself, which deals with the investigation of a series of sites in the Capertee Valley in the Glen Davis area (26, No. 6. Pp. 197-246 + Plates 11-24. Sydney: The Australian Museum, 1964. 16s. 6d.). There are a number of excellent illustrations of the finds. The results show a definite development in the stone working during the occupation of the sites and the final assemblages are rich in types of tool. They include blades with notched edges, side and end scrapers, pointed blades, cores, microlithic tools of various types and pounders. Most of the article, of necessity, is given up to a description of the finds. It is an article not to be missed by students interested in the early prehistory of Australia.

Pyrethrum from New Guinea

As is well known, pyrethrum is a natural insecticide having the unique advantage of toxicity to almost all insect pests, but harmless to man and animals. No synthetic product has so far been discovered that is able to match, let alone to rival, its peculiarly rapid properties in problems of insect extermination. Yet we learn that at present there exists a world shortage of pyrethrum extract for this purpose, which has grown increasingly acute with a general rise in living standards, according to an article in a recent issue of *Albright Magazine* (Albright and Wilson, Ltd., London, October 11, 1965). The firm of Stafford Allen, Ltd., one of the Albright-Wilson group, with long-established experience of the pyrethrum business, in collaboration with the administration of the Territory of Papua and New Guinea, has set up a cultivation centre for production of pyrethrum insecticide on a large scale in the Western Highlands of New Guinea, complete with a modern extraction plant, at Mount Hagen, a few hundred miles north-west of Port Moresby, in what looks like most uninviting country; it is, in fact, quoted as "... a vast fertile plain ringed by mountain walls soaring to over 15,000 feet above sea-level and inhabited by natives still in the Stone Age". Pyrethrum will only flourish and produce economic quantities of its toxic ingredients under specific optimum conditions: a combination of altitude, climate and soil; this particular project in New Guinea is satisfied by all three. It is said that altitude is the most important single factor to successful cultivation, but such benefits as stable temperature, an equable balance of sunshine and rain, and equal hours of day and night at all seasons of the year, are material items. Such favourable environmental circumstances make it practicable to plant a selected strain of pyrethrum flowers in different areas, thereby ensuring that the harvest period is spread over the whole year, a vital factor to the continuous operation of the extraction plant and, incidentally, to the employment of a needy native population. This project is the first major industrial operation in this remote area of the Western Highlands of New Guinea. The capital investment involved in bringing it to fruition is in the region of £250,000, and to handle the scheme a new company—Stafford Allen (New Guinea) Pty., Ltd.—has been formed. The coloured illustrations to the article help to convey some idea of the territory concerned, including the pyrethrum flower involved (which resembles an ordinary marguerite) and of the natives who work in these somewhat unusual fields.

Hospital Lighting

DOCTORS examining patients and pathological specimens in hospitals frequently have to note accurately the colours

of the objects they examine, whether it be the skin of the patient, or lesions on it, the conjunctivae of the eyes, the tongue, or the mucous membranes of the mouth. A good example occurs in a slight case of jaundice. Daylight is best for this purpose, but it is not always available, and it is therefore important that artificial lighting used in hospitals should not distort the colour of anything examined by the doctor. For this reason, the Medical Research Council and the Building Research Station of the Ministry of Technology (formerly of the Department of Scientific and Industrial Research) have investigated this problem at Sheffield Royal Infirmary. Fifteen lamps, both fluorescent and tungsten filament, were tested, and the results are now published under the title *Spectral Requirements of Light Sources for Clinical Purposes* (Medical Research Council. Memorandum No. 43. Joint Committee on Lighting and Vision. Pp. vii + 56 + 2 plates. London: H.M.S.O., 1965). This clearly shows that the fluorescent lamps are better not only because they give the smoothest distribution of light and the colour appearances of warm sunlight, but also because they are more economical. Any reputation they may have gained for distorting colour is due to the use of lamps with a grossly uneven distribution of energy over the spectrum. The report proposes a detailed specification for a fluorescent lamp suitable for general use, and it also hopes that this will help manufacturers to supply lamps satisfactory for the hospital service.

Glove Damage as a Cause of Wound Infection

THE use of rubber gloves during surgical operations became general about 1900. In 1939, Devenish and Miles emphasized that damage to rubber gloves could lead to infection of operation wounds. In recent symposia concerning nosocomial infection, defects in rubber gloves were considered to be of significance in the development of wound infection. The object of an investigation by Palle Gad was to obtain an estimation of how frequently wound infection originates from bacteria on the hands of the operating staff (*Danish Medical Bulletin*, 12, No. 1; March 1965). Examination of the wounds following 433 'clean' operations, of the 3,125 rubber gloves used in these operations and of the bacterial flora of the hands which had worn 692 damaged gloves, revealed no connexion between the glove damage, the bacterial flora and the wound infections observed.

Aldosterone in Myocardial Infarction

THE urinary excretion of aldosterone in healthy adult Indian males was recently estimated in order to establish the normal standard. This value ranged from 6.5 to 19.2 $\mu\text{g}/24\text{ h}$ (*Ann N.Y. Acad. Sci.*, 118, Article 11: *Role of Aldosterone in Myocardial Infarction*. Pp. 537-554. New York: New York Academy of Sciences, 1965). The value was two to three times higher in acute uncomplicated myocardial infarction. Sodium-restricted diet and controlled posture in normal individuals caused a rise in the urinary excretion of aldosterone, but the rise was much less than that observed in myocardial infarction. R. B. Aroa of the All India Institute of Medical Sciences, New Delhi, has also shown that urinary aldosterone excretion in normal, healthy dogs fed a constant diet and later on in the same dogs, with experimental myocardial infarction, revealed a similar increase in the absence of liver damage. Animal experiments also preclude the possible influence of drugs used in myocardial infarction on the level of urinary excretion of aldosterone. Extrapolation of the findings from animal experiments permits the hypothesis that increased urinary excretion of aldosterone in patients with myocardial infarction is to be attributed mainly to the myocardial infarction, and not to the associated factors, that is, diet, drugs, and posture. The rise of sodium concentration in the infarcted myocardium appears to have a causal relationship with the aldosterone-induced arrhythmia in myocardial infarction.

Melville on Macromolecule Chemical Industry

IN an article in *Chemistry in Britain* (1, 404; 1965), based on his lecture at the Royal Institute of Chemistry conference earlier in the year, Sir Harry Melville compares three British industries which have to do with macromolecules. These are plastics, textiles and paper. In all of these there has been a tendency towards bigger enterprises. In plastics, for example, there were in 1958 six enterprises with more than 1,500 employees. The plastics industry has been one of the fastest growing sectors of British industry, with a volume production now greater than the total usage of all non-ferrous metals. There has been little tendency to diversification: nearly all the plastics now manufactured commercially have been known and manufactured for many years. Although there is plenty of evidence that research and development expenditure in an industry contributes directly to its profitability and growth, research and development are becoming relatively more expensive. Indeed, in the older and empirically developed paper and textile industries there is no certainty that increased research and development expenditure would be fruitful. The search for precise criteria for decisions on research and development expenditure should not obscure the value of innovators. These are rare people and should be encouraged in industry, even though they may not conform to the pattern which makes life easy for their administrators.

University News:

Belfast

THE following appointments have been made: *Professorships*, Dr. W. O. Brown (agricultural chemistry); Dr. J. C. Murdoch (crop and animal husbandry); Dr. R. K. McKee (mycology and plant pathology); *Lecture-ship*, Dr. W. C. Beattie (electrical engineering).

Birmingham

THE following appointments have been made: *Senior Lectureship*, Dr. C. E. Oxnard (anatomy); *Lectureships*, Dr. M. H. B. Hayes and Dr. A. J. Waring (chemistry); *Research Fellowships*, A. N. Bramley (mechanical engineering); J. L. Godman and B. H. Rees (chemistry); R. S. Lowery (microbiology).

Announcements

A MEETING on "The Degradation of Biological Macromolecules", organized by the Physical Biochemistry Group of the British Biophysical Society, will be held in Oxford on January 11. Further information can be obtained from Dr. A. R. Peacocke, St. Peter's College, Oxford.

A CONFERENCE on "Solid State Physics", organized by the Institute of Physics and the Physical Society, will be held in the Manchester College of Science and Technology during January 4-7. Further information can be obtained from the Meetings Officer, Institute of Physics and the Physical Society, 47 Belgrave Square, London, S.W.1.

A SYMPOSIUM on "Recent Advances in the Development, Production and Utilization of Medicinal and Aromatic Plants in India", under the auspices of the Central Indian Medicinal Plants Organization, will be held at Lucknow during January 12-14. Further information can be obtained from Dr. S. C. Datta, Central Indian Medicinal Plants Organization, 4 Sapru Marg, Lucknow.

ADDENDUM. In the communication entitled "Social Companions and the Mother-Infant Relationship in Rhesus Monkeys", which appeared on p. 301 of the October 16, 1965, issue of *Nature*, the following legend should have accompanied the illustration:

Fig. 1. Number of half-minutes in which the infants were recorded off their mothers, expressed as a percentage of number of half-minute periods for which they were watched. Shaded area shows the range for the isolate infants. Dotted area shows the range for group-reared infants. ○, Median for isolate infants; ●, median for group-reared infants

ELECTROMAGNETIC DISTANCE MEASUREMENT

THE International Association of Geodesy, on the invitation of the Royal Society of London, held a symposium on "Electromagnetic Distance Measurement" at Oxford during September 6-10, 1965. The precise measurement of long distances on the Earth's surface, and also to artificial satellites, has become an increasingly important technique of geodesy during the past twenty years. Numerous instruments are now available commercially for this purpose, using either modulated light or microwave beams, and much research is going on, including work on the application of lasers to distance measurement.

These instruments have created new problems for geodesists who seek accuracies of one or two parts per million. The speed of light is a vital parameter in the calculations, and the effect of atmospheric refraction is most important. The precise determination of the mean refractive index for long lines through the atmosphere at present constitutes the most intractable problem. A further complication with microwaves is that they are reflected from surfaces below or adjacent to the line measured, causing difficulties in observation and uncertainties in the final determination.

It was to investigate these and other associated problems, and to evaluate the available instruments, that Special Study Group No. 19 of the International Association of Geodesy was formed in 1958. The symposium was convened by Major-General R. C. A. Edge, president of the Study Group (and now director-general of the Ordnance Survey), to provide a forum in which the geodesists' problems could be discussed with physicists and meteorologists from all over the world whose work had an important bearing on the subject.

The working sessions covered microwave instruments, electro-optical instruments, propagation problems, laser applications, airborne systems, ranging to artificial Earth satellites, and finally the precise measurement of distances of the order of 1 km or less to accuracies better than one part per million. This last is a newcomer to the work of the Study Group, but one of increasing importance in precise engineering, as for example in the construction of particle accelerators. Plans are now being made to publish a full record of the proceedings, including discussions.

Further information concerning the symposium may be obtained from the Director-General of the Ordnance Survey, Leatherhead Road, Chessington, Surrey.

AUSTRALIAN BIOCHEMICAL SOCIETY MEETING

A MEETING of the Australian Biochemical Society was held at Monash University, Clayton, Victoria, during August 24-27. It took the form of general research papers and symposia on protein structure, function and synthesis—the latter in relation to the genetic apparatus—and the genesis and function of membrane systems. Speakers from overseas and Australia were invited.

S. Moore discussed the chemistry of the catalytic site of ribonuclease with particular reference to the histidine residues at positions 12 and 119 and the lysine residue at position 41. The proportion of each histidine alkylated at nitrogen-1 of histidine 119 and at nitrogen-3 of histidine 12 was found to vary with the chain-length and the particular isomer of the alkylating agent. Charged substitution (carboxymethyl) of lysine-41 lowered the rate of histidine alkylation, but an uncharged (carboxy-amido) derivative did not affect it. The spatial relationships of these three amino-acid side-chains as a part of the active centre can now be visualized.

The mechanism of action of certain hydrolytic enzymes as followed by kinetic analysis of the formation of acyl intermediates and their subsequent rate of decay was discussed by B. Zerner. In the case of chymotrypsin and trypsin the decay of the acyl derivative was found to be the rate-limiting step. The mechanism of hydrolysis by liver carboxylesterases, urease and certain other proteolytic enzymes seems to follow the same general chemistry of an acyl enzyme intermediate. He pointed out that the detailed chemistry underlying enzyme specificity is still unsolved.

E. O. P. Thompson gave an account of the accumulated information concerning keratin structure with particular emphasis on Australia's national product, wool. Urea and a reducing agent are required to disrupt the firmly bound structure. Subsequent alkylation of the thiol groups so formed gives protein fractions amenable to conventional separation methods. The large number of acetyl end

groups is of considerable interest. Three general heterogeneous classes of protein are present in wool—high sulphur, low sulphur and high glycine. The high sulphur proteins are found in the matrix between the fibrillar structures and may vary from 22 to 31 per cent with forced feeding. Serious attention is now being given to the bottom (growing) end of the wool fibres. There are suggestions that the high sulphur proteins are formed later than the rest and that consolidation of the protein system occurs higher up the fibre.

What was true and new about our oldest and best-known protein system—gluten—was amusingly discussed by M. V. Tracey. In latter years the separation methods successfully applied to other protein systems have been tested and shown to be not very useful with gluten. But the attempts have gone on. The protein as it occurs in flour has the original characteristics of the protein as synthesized, but with maturation of the grain, etc., subsequent alterations have been superimposed. Mr. Tracey, in opposition to the simplifiers, pointed out that, as isolated from the flour, the gluten complex has a range of molecular weights of 20,000 to many millions. Using common-sense arguments he pointed out that random polymerization through disulphide cross-linking would give rise to giant molecules. He argued further that an allo-polyploid with endosperm cells having three sets of chromosomes plus accumulated mutations would not be expected to synthesize storage proteins of simple variety.

V. Moses discussed the observation that proteins synthesized in *E. coli*, after depleted cells have been supplied with nutrients, appear at different rates. This discrimination was interpreted in terms of stability differences in the related molecules of *mRNA*. He raised the question of the control of protein synthesis when the related *mRNA* is of the stable kind. If it is exercised, control in such a situation must be at a later stage than transcription of DNA. B. W. Holloway reviewed the evidence relating to a general operon hypothesis for control

of genetic expression of clusters of related genes. He concluded that in *E. coli* and *Salmonella typhimurium* up to 70 per cent of the genes showed some clustering, but that in *Pseudomonas aeruginosa* it is quite rare. It was expensive, he thought, for each gene to have its own operator and so, without clustering, it was reasonable to expect regulation of enzyme synthesis at the translation level—a point arrived at by the previous speaker. W. H. Elliott also suggested control of ribonuclease synthesis in *Bacillus subtilis* at a stage later than transcription. He has found that actinomycin stimulates ribonuclease production—an observation which would seem to preclude control at the transcription stage. The presence in the cell of a firmly complexing inhibitor of the active ribonuclease secreted by this organism suggests that this enzyme is synthesized close to the cell membrane—from which it is released to the medium. Dr. Elliott also gave evidence for the synthesis of the exo-enzyme α -amylase close to the cell membrane.

The regulation of RNA biosynthesis in general was reviewed by L. R. Finch, who added the idea that the present concepts of the utilization of mRNA for protein synthesis, before its own transcription from DNA was completed, allow possible alternative methods of repression not immediately connected to the operator region. He saw combination of the repressor with the nascent peptide chain as offering more specificity than the simple operator region hypothesis.

G. L. Ada spoke of the structure of immune γ -globulin and the problems besetting the investigation of the mechanisms controlling the synthesis of antibody by cells from the spleen and lymph nodes. The heterogeneous nature of the lymph nodes makes conventional methods of following protein synthesis difficult to interpret in terms of antibody synthesis, but the use of radio-autography and specific fluorescent staining offers hope. Injection of powerful bacterial antigens labelled with radio-iodine into rats leads to the uptake of less than four molecules of antigen per plasma cell. It was inferred that intact antigen does not act as a template in the synthesis of antibody. The association of antigen with RNA as being involved as an intermediate in the antigenic response was discussed.

Attempts to define the number and function of proteins coded for by poliovirus RNA after infection were discussed by P. D. Cooper. Mutants resulting from treatment with 5-fluoro-uracil were selected for heat-defectiveness over the small range of temperature of 37°–39.5° C. Five to six genes affecting host cell metabolism have been detected, but the mechanism of their action is as yet little understood. He suggested that the proteins formed as gene

products in the mutants differed in perhaps one amino-acid only and that this alteration allowed easy temperature deformation.

J. K. Pollak discussed his work on the origin of the endoplasmic reticulum in developing and regenerating liver. He presented evidence supporting the formation of the reticulum from precursor granules (reticulosomes). These consist mainly of protein which combines with phospholipid to form stable complexes resembling a membranous reticulum. D. E. Green discussed his accumulated knowledge of the methods of separating and re-forming the structural protein phospholipid complexes of mitochondria. He also discussed the evidence for the association of the integrated enzyme systems with structural components of the mitochondria. The localization of the effect of chloramphenicol on the formation, in *S. cerevisiae*, of completed mitochondria with respect to a marked decrease in the number of cristae and of certain mitochondrial enzymes was discussed by A. W. Linnane. The organism grows extremely well on the readily fermentable glucose. His results suggest specificity in the effect of chloramphenicol on mitochondrial development. The synthesis of chloroplasts with respect to regulation, the greening process and the involvement of contained DNA, RNA was discussed by R. M. Smillie. Once again chloramphenicol was reported to show specificity in its effect on the synthesis of protein in the developing organelle.

Using mitochondrial swelling as a measure of substrate uptake, J. B. Chappell presented results which were consistent with the presence of carriers for malate and succinate dependent on phosphate and for citrate being dependent on the presence of L-malate in addition. He sees the process of uptake as being by exchange diffusion. Many in the audience came to sensible grips with mitochondrial swelling for the first time.

T. P. Singer summarized the existing knowledge on the complexities of NADH₂ dehydrogenase, with its flavin, non-haem iron and labile sulphur. Its functional position in the electron transport chain in relation to phospholipid and the modifications of its properties by heat and organic solvents and mercurials were discussed.

L. P. Vernon and N. K. Boardman discussed chloroplasts and their functional components which are concerned in electron movement following photochemical excitation. They considered these components with respect to the individual steps and pathways involved and with respect to sub-units having definable activities. Knowledge of chloroplast function now seems to be comparable in depth with that of mitochondria from animal tissues.

F. J. R. HIRD

CONTROL OF BIOLOGICAL DEVELOPMENT

THE seventh International Embryological Conference, sponsored by the Editorial Board of the *Journal of Embryology and Experimental Morphology*, was held in London during September 6–10. Three different forms of scientific communications were used: twelve main papers, five discussion groups and some eighty demonstrations were presented by scientists from twenty countries. The control of development formed the major topic of the meeting, since classical embryology is now being re-interpreted in terms of the mechanisms of control of protein synthesis by the genes. Development, of course, requires that a sequence of changes occurs in the types of synthesis carried out by a developing cell. Dr. S. Brenner (Cambridge) introduced the session on the genetics of embryogenesis by discussing the possible control mechanisms whereby a series of cistrons could bring about the sequential series of changes in synthesis required in differ-

entiation. Dr. H. MacGregor (St. Andrews) described recent work on the lamp-brush chromosomes found in newt eggs during their formation. These chromosomes are intensely concerned with the synthesis of materials which form the egg.

However, genetic control systems of embryogenesis tend to fail even if the chromosome number is haploid or polyploid rather than diploid. Prof. L. Gallien (Paris) described a number of instances of polyploidy in amphibia and correlated these abnormalities and examples of aneuploidy with the type of failure of development observed.

Dr. L. Hamilton (London) spoke on her work on the genetic factors which may be involved in the 'haploid syndrome' found in haploid amphibian embryos. This syndrome is characterized by oedema and a tendency to failure of development and is very variable in its expres-

sion. The question is whether the syndrome is due to a lack of hybrid vigour, which would normally be found frequently in a diploid wild-type population, to the presence of certain lethal genes, active only in the haploid state, or to other causes. If it were due to the absence of hybrid vigour the syndrome would be expected to appear at equal intensity in all haploids. If, however, it were due to certain specific genes, all animals obtained by nuclear grafting from the same clone of nuclei would show the syndrome to the same extent. Dr. Hamilton reported that on performing this experiment haploid animals were obtained which showed some variation in the extent of the haploid syndrome. This result suggests that the genetic explanations suggested here are incorrect.

Gene action in development is, of course, expressed in the control of protein synthesis, and another session was devoted to protein synthesis in embryos. Dr. P. N. Campbell (London) introduced the next session by outlining the biochemical background and problems in the investigation of this topic in embryos. He pointed out that embryos might present a fruitful field for the investigation of control mechanisms since a number of morphogenetic interactions are known to involve substances, some of which are proteins, which alter the general types of synthesis in target cells and which may act directly on the genetic system.

Prof. J. Brachet (Brussels) described histochemical and autoradiographic work on the localization of protein synthesis and production of messenger RNA in the early stages of amphibian development. He discussed the ways in which localization of certain substances in certain parts of the embryo might bring about locally different types of synthesis, and also considered the possibility that part of the protein synthesis might be under the control of extranuclear DNA. The amphibian egg is remarkable in that at the start of development there is roughly 1,000 times as much DNA outside the nucleus as within it.

Prof. A. Monroy (Palermo) reported his experiments on the initiation of protein synthesis in echinoderm embryos immediately following fertilization. There appear to be two separate waves of protein synthesis, one of which appears at gastrulation, as in many other embryos; but the other starts immediately after fertilization and appears to be connected with the activation of the egg.

Prof. Flickinger (Buffalo) described his experiments on the priming of RNA synthesis in different parts of the amphibian embryo at gastrulation. He found that priming required DNA or chromatin and suggested that protein from chromatin might tend to act as an inhibitor. Using this system he found that the endoderm appeared to be most active in synthesis of RNA. This result is rather surprising in view of the fact that simpler techniques had suggested that the dorsal lip cells were most active in RNA synthesis. Dr. B. Mintz (Philadelphia) chaired a discussion group on the initiation of synthesis (in particular protein synthesis) in the mammalian egg. The chief speakers were Dr. C. Austin (Tulane) and Dr. D. Szollosi (Philadelphia).

Another important topic at this meeting was the subject of developmental neurology. Prof. V. Hamburger (St. Louis) spoke on his work on the demonstration of spontaneous intrinsic rhythmic activity in the spinal cord of chick embryos. By separating parts of the spinal cord from the brain very early in development, it was nevertheless possible, later, to obtain motor activity in the isolated portions of the cord. This result suggests that these activities can surprisingly develop independently of control from higher centres of the central nervous system. Prof. M. Singer (Cleveland, U.S.A.) reported on his work on the control of limb regeneration in amphibia and reptiles, and demonstrated that whether or not regeneration took place depended in part on a certain threshold of nerve mass in the stump being exceeded. The discussion group on developmental neurology was chaired by Dr. A. F. Hughes (Bristol). It opened with a review by Dr. Rita

Levi-Montalcini (St. Louis and Rome) on the sequence of her researches on the nerve growth factor. The two remaining main papers dealt with the problem of how the precise pattern of the wiring of the nervous system is established.

Dr. R. M. Gaze (Edinburgh) gave an account of his work on optic nerve regeneration in fish and amphibians, in which the restoration of the retinotopic projection of fibres of the optic nerve on to the optic tectum is charted by means of systematic retinal stimulation, and electrical recording from the tectum. Among other experiments, Dr. Gaze showed that if half the eye rudiment is removed in early *Xenopus* tadpoles and a corresponding half eye grafted in its place, then fibres from the original half retina ultimately may project over the whole of the tectum. On the other hand, after hemisection of the optic nerve in the adult goldfish, there is no evidence that the projection of the remaining optic fibres spreads beyond its own half of the tectum.

The third main speaker was Dr. George Szekely (Pécs), who described recent experiments on limb movement in both urodeles and birds in which heterotopic transplantation of regions of the spinal cord were made at early stages of development. The final pattern of limb movement is greatly influenced by the source of the grafted cord. Thus, if lumbar cord is grafted at brachial levels in the chick, the wings of the young adult bird are unable to flutter when the animal is allowed to fall. Dr. Harkmark, Dr. Drachman and Prof. Singer also contributed to this discussion.

Other speakers in the main sessions were Dr. O. Vyasov (Moscow), who reported work on the immunology of embryos, Dr. D. Yaffe Rehovoth, Israel, who described his experiments on the factors affecting muscle differentiation, and Dr. T. Humphreys (Cambridge, U.S.A.), who spoke on his experiments on factors controlling the specificity of sponge re-aggregation. Dr. N. Verdonk (Utrecht) and Dr. T. Dettlaff (Moscow) spoke on their work on early stages of molluscan and fish development respectively. Prof. Pasteels (Brussels) read a paper by Prof. J. Mulnard (who was unable to attend) on the effect of ooplasmic segregation on the development of trophoblast or embryo in the mammalian embryo.

Three other discussion groups were held. Dr. Goss (Providence, U.S.A.) introduced a discussion on the control of organ size. Dr. A. Coulombre (Bethesda, U.S.A.) talked on his work on the control of lens and retina growth, in which he had showed by operative procedures that interactions took place between lens and retina to control their growth. Prof. W. Bullough (London) spoke of his work on the control of mitosis by chalcones. In the second group, J. Dingle (Cambridge) introduced a discussion on the role of lysosomes in development. He suggested that, though the concept of the lysosome as a discrete intracellular organelle containing a number of hydrolytic enzymes has greatly stimulated biochemical work on the isolated particle, the functions of the lysosome are only slowly beginning to emerge. The participants in the discussion group on the role of lysosomes in development clearly emphasized the importance of lysosomal enzymes in the dynamics of tissue synthesis and degradation during embryonic development.

Dr. Scheib (Paris) presented electron micrographs demonstrating the presence of numerous autolysosomes in the regressing Müllerian duct. These bodies, which are a form of lysosome concerned with digestion of other organelles, were large and complex and contained high acid phosphatase activity. Prof. Weber (Berne) and Dr. Eeckhout (Louvain) showed lysosomal particles to be present in the metamorphosing tadpole tail; continued synthesis of lysosomal hydrolases, particularly of protease, was found to be important in the process of regression. That changes in lysosomal activity or stability might affect other cellular functions, notably cell division, was suggested by Dr. A. C. Allison (Mill Hill). The final

paper, by Dr. M. Prestige and Dr. A. Hughes (Bristol), dealt with the possibility that lysosomes may play a part in cell degeneration in the central nervous system.

The very active discussion of the papers emphasized the present interest in the role of lysosomes in pathology as well as in normal physiology and embryology.

The third group was chaired by Prof. E. Wolff (Nogent-sur-Marne); in the introduction to a discussion on interpretation of epigenetic malformations he pointed out that numerous physical or chemical factors, when applied at the same stage of development, produce the same types of malformations, such as cleft palates. On the contrary, other drugs have a specific teratogenic effect. The action of thalidomide on human fetuses has dramatically confirmed this point of view. The question arises of how these two different mechanisms can be explained.

Dr. W. Landauer (London) described his work on some drugs such as insulin. Dr. J. Ebert and Dr. M. Reporter (Baltimore) reported their work on the action of actinomycin A on differentiation of muscles *in vivo* and *in vitro*. This substance specifically inhibits the differentiation of the heart of the chick embryo *in vivo* and of muscle fibres in *in vitro* cultures. The authors extracted from the mito-

chondrial fraction of tissues of the adult chick (liver and muscles) a protein that prevents the teratogenic effect of actinomycin A. As a consequence this substance may be considered as inhibiting the formation of a protein essential in muscular differentiation.

Finally, Dr. Kirrmann (Paris) showed that X-rays—a non-specific teratogenic factor—affect general respiratory metabolisms, which result in a decrease of oxygen consumption of the tissues. This metabolic effect as well as the teratogenic action of X-irradiation can be prevented by anoxia or by substances—such as cysteamine—which are able to combine with free radicals arising in the tissues as a result of the ionization of water. So we can assume that the two different mechanisms of activity of teratogenic substances may be related to whether they affect general or specific metabolisms.

In addition some eighty demonstrations were presented by members of the conference, ranging over all branches of embryology. The conference was made possible by the generosity of the International Union of Biological Sciences, the Royal Society and by a number of industrial organizations. The eighth International Embryological Conference will be held in Berne, Switzerland, in 1967.

SEAWEED RESEARCH

THE fifth International Seaweed Symposium was held at Dalhousie University in Halifax during August 25–28. The purpose of these conferences has been to foster original research, both fundamental and applied, in the field of marine algae and to facilitate the presentation of such investigations. Previous symposia have been held at Edinburgh, Trondheim, Galway, and Biarritz, on a triennial cycle. In a programme of four invited lectures and 55 original communications, the topics were evenly divided between botanical, chemical, and applied aspects. A symposium within a symposium developed on the subject of algal polysaccharides.

In discussing the seaweed industry of the future, F. N. Woodward (Scotland) emphasized the possibilities of mass culture as a source of protein, the cultivation of areas for selected species as in Japan, the great need for mechanization in harvesting and drying, and the possibilities of further applications of the unique algal polysaccharides in agriculture, industry, and medicine. The use of mustard, *Sinapis alba*, as a test plant with which to assess growth response to seaweed extracts was described by Challen and Hemingway (United Kingdom). Stephenson (United Kingdom) reported specific effects from the use of liquid seaweed fertilizer as contributing to enhanced resistance of some field crops to frost, to pathological fungi, as *Botrytis* on strawberries, and to animal parasites, such as aphids on beans and sugar beets.

In a masterly lecture on recent studies of the polysaccharides of Agarophytes, Araki (Japan) described his investigations of the chemical constitution of agarose and agaropectin. Sulphate groups as half-esters were established in agaropectin only. The remarkable finding of variable but appreciable amounts (1–20 per cent) of 6-O-methyl-D-galactose in agarose was reported. Pyruvic acid was confirmed as a constituent of only two agaropectins. In agarose the molar ratio of D-galactose + 6-O-methyl-D-galactose to 3,6-anhydro-L-galactose was always unity.

Anderson and Rees (Scotland) have found that carrabiose units account for 88–99 per cent of the molecule of κ - and λ -carrageenans based on the products after methanolysis of native and alkali-treated material. A new, widely distributed, sulphated heteroglycan, isolated first from *Ascophyllum*, has been discovered by Larsen and Haug (Norway) and named ascophyllan. It contains fucose, xylose and a uronic acid. The uneven distribution of

mannuronic and guluronic acids in the main chain of alginic acid was postulated by Haug and Larsen (Norway) from investigations of partial hydrolysis with oxalic acid. The isolation of specific κ - and λ -carrageenases from *Pseudomonas carrageenovora* was reported by Yaphe *et al.* (Canada).

The finding of pure poly-N-acetylglucosamine as the only constituent of the extracellular fibres of the diatom, *Thalassiosira fluviatilis*, by McLachlan, McInnes, Falk and Craigie (Canada) provides the only instance in Nature of the occurrence of this substance in pure form. It has been renamed chitan. Two other unusual compounds were reported as occurring in marine algae—dimethyl- β -propiethetin and 2,3-dibromobenzyl alcohol-4,5-disulphate.

Black *et al.* (Scotland) described a survey of many of the Rhodophyceae as possible sources of the carrageenans. Marked variations in yield, ratio, optical rotation, and chemical composition were recorded. Sharp fractionation into κ - and λ -components with potassium chloride was not always achieved, for example, in *Eucheuma spinosum* and *Polyides rotundus*. Fleming, Hirst and Manners (Scotland) have found notable similarity in the soluble and insoluble forms of laminarin except that the former exhibits a greater degree of branching. Painter (United Kingdom) presented evidence that the sulphate group in the galactose of κ -carrageenan and fucellaran is more or less randomly distributed over all available hydroxyl groups in the carbohydrate chains and not only attached at C-4 as previously believed.

The unexpected property of some seaweeds to “fix” radioactive ions was described by Czapke (Poland) and Skoryna *et al.* (Canada). The present explanation is based on ion-exchange with soluble or insoluble alginate. This property was applied as an index of the radioactivity of the aqueous environment and as a means of inhibiting absorption of strontium-89 in the gastro-intestinal tract of animals.

In a well-illustrated study of the tissues of *Fucus*, McCully (United States) pointed out differences between the walls of the outer epidermal cells with their amorphous outer layer, the underlying parenchyma and the central medulla with its reticulum of branched primary filaments and secondary intrusive fibres, all these being embedded in a mucilaginous matrix. Observations with the light microscope, using specific stains and extended by elector

microscopy of adjacent sections, suggest that fucoidin is confined almost entirely to the mucilaginous matrix, while cellulose and alginic acid are in well-defined bands in the fibrillar portions of all the walls. A similar topic was treated by Baardseth (Norway), who examined the localization and structure of alginate gels from *Ascophyllum*. He believes that alginates exist mainly as intercellular substances at all stages of development, and he finds no evidence for two walls in brown algae, a primary wall of alginate and a secondary wall of cellulose.

Chapman (New Zealand) discussed the physiological ecology of seaweeds in a general lecture. For a number of the macroscopic algae which are found on the coasts of Australia and New Zealand, Chapman showed how physical factors which affect their distribution can also effect morphological variations. He gave many experimental data suggesting that changes in light, temperature, depth, desiccation, etc., could influence the ability of the algae concerned to function at their optimum and hence could be responsible for the limits of distribution.

Kain (United Kingdom) showed that the lower level of *Laminaria hyperborea* in the Isle of Man may be determined partly by biotic factors: removal of colonies of *Echinus esculentus* from the lower limits of beds of *L. hyperborea* and *Saccorhiza polyschides* has resulted in new algal growth over rocks at a level which remained bare when *Echinus* was present. Leighton, Jones and North (United States) have developed a method of treatment with quicklime to control the infestation of beds of *Macrocystis* by such sea-urchins in the Pacific Ocean. Many phaeophyceean genera are known to produce tannins, and Conover and Sieburth (United States) gave evidence to show that these metabolites may influence the ability of certain organisms to grow in confined bodies of water.

In a session on specialized botanical topics, Anderson and North (United States) described ways in which estimates of the extent of sporing in *Macrocystis* have been made *in situ*. For isolated plants, sporlings have been found up to 5 m away, which suggests that the spores sink relatively quickly and do not wash about in the sea for any great length of time. Conway (Scotland) described the extensive sporing of species of *Porphyra* and the microscopic perennating phases into which the spores develop. Such phases may be of considerable ecological importance to this widely distributed genus. Aziz (Pakistan) reported,

for the first time, sexual reproduction in *Acrochaetium liagorae* Borg.

In one of two sessions devoted to the algal flora of the Antarctic, Lamb (United States) described the pattern of distribution seen in the supra-littoral, littoral and infra-littoral zones at the Argentine base at Melchior. Early in the southern summer almost no vegetation is visible on the littoral rocks. Once colonization begins in the gullies, development is very rapid and spreads across the zone. Examination of the infra-littoral by SCUBA diving showed marked zonation with some of the major algae, including *Desmarestia*, down to 30 m. Zaneveld (United States) described surveys carried out along the coasts of Ross Island and Victoria Land, Antarctica, often through enlarged seal holes. These showed that large algal beds were present at depths between 6 and 35 m, with red algae, such as *Phyllophora antarctica*, *Iridaea obovata* and *Phycodrys quercifolia*, as the dominant species. Light measurements emphasized the paucity of light in such a habitat (about 1.1 per cent of the surface values) and showed that benthic algae are capable of photosynthetic production under fast ice with a coverage of 9–10 months.

Friedmann (Israel) described the occurrence in Mediterranean waters of numerous gametophytes of *Padina pavonica* and of the Indo-Pacific species *P. gymnospora*. Much variation in the occurrence of bisexual and unisexual forms is found and there are indications that the variation in different populations is controlled by ecological factors. Moss (United Kingdom) reported experimental work which indicates the importance of the large apical cell in *Fucus vesiculosus*. Round (United Kingdom) has observed rhythms in migration of *Euglena obtusa* and of certain diatoms and the effect of varying the normal day-length pattern.

Most of the papers presented will appear in the official proceedings to be published as a separate volume by the Pergamon Press of London in 1966. There were 220 at the symposium who registered from 25 different countries. During the symposium a meeting of the International Phycological Society was held. The sixth symposium will be held in Spain in 1968, according to present plans. A permanent secretariat for the symposia has been set up in charge of Mr. E. Booth, Institute of Seaweed Research, Inveresk, Midlothian, Scotland.

A SUGGESTED PHENOTYPIC CLASSIFICATION AND TERMINOLOGY FOR ENZYME MUTANTS IN MICRO-ORGANISMS

By DR. J. F. COLLINS*, DR. J. MANDELSTAM, PROF. M. R. POLLOCK, F.R.S.*, DR. M. H. RICHMOND* and DR. P. H. A. SNEATH†

National Institute for Medical Research, Mill Hill, London

THERE is now a large and increasing number of different types of enzyme mutant being isolated among micro-organisms. The very wide range of activity levels and degrees of induction manifested emphasizes the need for some general phenotypic classification, based on enzymatic function, for indicating their physiological properties.

A convenient scheme can be obtained by classifying strains both according to their induction response and according to the maximum level of enzymatic activity expressed (Table 1). It is suggested here that four grades of performance with respect to each of these two independently variable functions (giving sixteen different

phenotypes) would, in this respect, cover the essential properties of most strains ever likely to be recognized. In this scheme, the various categories are classified, purely on the basis of their phenotypic characters, by reference to the basal and maximally induced enzyme activities of the parent wild-type strain of micro-organism. 'Non-inducible' thus corresponds to 'constitutive' in the sense originally used by Karstrom¹; the definition depends, therefore, on absence of induction response and not on level of enzyme activity.

Certain adjustments and additions to the symmetrical scheme that emerges from the foregoing considerations have inevitably arisen. It is scarcely practicable, for example, to abandon the term 'constitutive', which is well-established, and replace it by 'non-inducible'. But it is reasonable to suggest that it be used in its original

* Present address: Department of Molecular Biology, University of Edinburgh.

† Present address: Medical Research Council Microbial Systematics Research Unit, University of Leicester.

sense of non-inducible and not be restricted (as some workers would doubtless still insist) to strains where a certain 'high' level of enzymatic activity is reached without induction. For similar reasons, it is probably preferable to retain the term 'semi-constitutive' rather than change to 'semi-inducible'. But in that case it would be essential—in conformity with the definition of 'constitutive' used here—not to restrict its use (as previously²⁻⁴) to one particular type of 'semi-inducible'—namely, strains with raised basal activity and 'magnol' levels after induction^{3,4}. Moreover, to use the full terminology set out in Table 1 would be absurdly cumbersome.

The various categories finally suggested are therefore classified in a more practical and realistic form as follows.

(I) FULLY INDUCIBLE. Normal (that is, wild-type (WT)) induction ratio. (a) Magno-inducible: max. induced level similar to max. induced WT level. (b) Meso-inducible: max. induced level less than max. induced WT level but greater than uninduced (basal) WT. (c) Micro-inducible: max. induced level equal to, or less than, basal WT level. (d) Inducible 'Hypers': max. induced level above max. induced WT level.

(II) STRICTLY CONSTITUTIVE (= 'non-inducible' in Table 1). Induction ratio = 1.0. (a) Magno-constitutive: level formed by most constitutive strains (normally rather greater than max. level of maximally induced magno-inducible WT). (b) Meso-constitutive: less than magno-constitutive level but greater than basal WT level. (c) Micro-constitutive: equal to (= 'baso-constitutive'), or less than, basal WT level. (d) Constitutive 'Hypers': greater than level attained by the common ('magnol') constitutives.

(III) SEMI-CONSTITUTIVE (= 'semi-inducible' in Table 1). Induction ratio greater than unity but less than WT.

(IV) SUPER-INDUCIBLE. Induction ratio greater than WT.

(V) NEGATIVE. No detectable enzymatic activity, with or without induction.

Examples of all the classes mentioned in the foregoing list, with the exception of the 'super-inducibles' (included for logical symmetry), are known in one or more of the systems already being examined.

Within the 'micro-constitutive' group a sub-section ('baso-constitutives') is suggested for strains producing levels corresponding to normal wild-type uninduced activity. The reason for this is that in the penicillinase series so far examined in this laboratory there appears to be a possibly significant degree of 'clustering' around this level. It was considered that among micro-constitutives the complete inability to respond to induction from the basal WT level (six out of thirteen in a current series of penicillinase mutants of *Bacillus licheniformis*) might reflect some significant physiological and/or genetic property (cf. also the *i^s*-super-repressed mutants in the *E. coli* β -galactosidase system⁵).

All comparisons are intended to be with respect to corresponding WT inducible strains or 'usual' magno-constitutive mutants (as defined in II (a)). Induced levels are measured after treatment with one particular inducer under standard conditions. Margins for significant

differences permitting relegation to the micro- and meso-groups must depend on assay techniques and reproducibility of enzyme titres in the particular system concerned. 'Hyper' strains (both inducible and constitutive) have already been isolated and described for the *E. coli* β -galactosidase system⁶. A separate group comprising all strains with no detectable enzymatic activity, even after treatment with likely inducer ('negatives'), must also be included, since they cannot logically be classified in any of the other groups. The other categories are self-explanatory.

It is, of course, recognized that such a classification cannot possibly persist indefinitely and that individual strains may have to be re-classified as techniques change and information accumulates. For example, increased sensitivity of enzyme assay methods may obviously lead to 'promotion' of a negative into a micro-inducible or micro-constitutive. Transfer of a micro-constitutive to the inducible class may be demanded by the discovery of a permease system or a completely new type of inducer. The existence or emergence of a new or unsuspected type of induction specificity is always a particularly tricky problem, since the original choice of inducer and induction conditions must inevitably be partly arbitrary. Strains may also change their category according to conditions. For example, mutants with properties consistent with the presence of a thermolabile 'repressor' have been isolated in both the β -galactosidase⁷ and penicillinase⁸ systems, being semi-constitutive at 50° C and magno-inducible at 35° C. Some groups may eventually need further subdivision, particularly where multiple superimposed mutations may have occurred.

It might further be argued that yet another class should be created for mutants where formation of the enzyme is specifically inhibited, instead of stimulated, by the standard inducer, and which would therefore give 'induction' ratios of less than unity. Such mutations have indeed been reported^{4,5}, and might perhaps be predicted on the Jacob-Monod⁹ hypothesis. In one sense, however, these would fall into the class of repressible systems. A formally analogous classification and terminology could indeed also be logically applied to normal repressible enzyme systems; 'irrepressible' being substituted for 'constitutive', 'derepressible' for 'inducible' and 'repression ratio' for 'induction ratio'.

The foregoing main scheme is based on one outlined eight years ago⁸ for classification of the *B. cereus* penicillinase systems. This was subsequently expanded for categorization of penicillinase mutants in staphylococci⁹, and further elaborated for similar mutants in *B. licheniformis*⁸. It is only strictly applicable to a series of mutant strains derived from the normal wild-type or the 'usual' magno-constitutive mutant, which can serve as reference standards. But it would seem possible also to use it (provisionally) for closely related wild-type strains within a species, taking the most active enzyme producer as a standard, so long as the arbitrary nature of the comparison was properly appreciated.

There is barely need to emphasize that, being based purely on phenotypic characters, the scheme will cut right

Table 1. SCHEME FOR PHENOTYPIC CLASSIFICATION OF ENZYME MUTANTS ACCORDING TO ENZYMATIC ACTIVITIES AND INDUCTION RESPONSE

Maximum induced level of activity		Induction ratio:*			
		= WT	= 1.0	> 1.0 < WT	> WT
		Inducible	Non-inducible	Semi-inducible	Super-inducible
= MWT	Magno-	Magno-inducible	Magno-non-inducible	Magno-semi-inducible	Magno-super-inducible
> BWT	Meso-	Meso-inducible	Meso-non-inducible	Meso-semi-inducible	Meso-super-inducible
< BWT	Micro-	Micro-inducible	Micro-non-inducible	Micro-semi-inducible	Micro-super-inducible
> MWT	-hyper	Inducible-hyper	Non-inducible-hyper	Semi-inducible-hyper	Super-inducible-hyper

WT, wild-type value. MWT, maximally induced wild-type level. BWT, uninduced (basal) wild-type level.

* Induction ratio = $\frac{\text{Differential rate of enzyme formation under defined standard conditions for maximal induction}}{\text{Differential rate of enzyme formation without inducer}}$

across any genotypic classification. The definitions are operative in relation simply to enzymatic activities and the response to induction. Indeed, its main value should be that it is not prejudicial to any particular type of further physiological or genetic analysis. For example, a negative or micro-constitutive may obviously arise either from a structural gene mutation, yielding an altered enzyme of low specific activity or from a 'polarity' mutation¹⁰ in an unknown location, which decreases the spontaneous rate of formation of normal (WT) enzyme. After all, most enzyme systems already capable of being examined in some detail phenotypically are not yet amenable to genetical analysis. Even in the classical enzyme systems of *E. coli*, the genetics remains controversial or obscure at many points.

Mutant Proteins ('Muteins')

In many instances, however, further physiological characterization, which may help in determining the genotype, can be achieved relatively easily. For example, it has already been suggested¹¹ that in strains where the mutation has resulted in the formation of an altered protein, analogous to the normal wild-type version, this product be referred to as a 'mutein'. This term may also help to avoid present difficulties^{12,13} arising over the use of the term 'CRM' (= 'cross-reacting material') as originally defined¹⁴. 'Muteins' may be presumed usually to arise from a gene mutation resulting in one or more amino-acid substitutions in one or more of any of the

polypeptide chains which constitute the specific molecule. For the moment, however, it might be preferable to allow the term to refer to any stable structural alteration, of mutational origin, within the molecule, and not restrict it to the product of any specific type or locus of mutation. Muteins may or may not possess any of the characters—enzymological, immunological or physico-chemical—of the corresponding wild-type protein. Their existence and recognition do not, therefore, depend on retention of immunological reactivity with anti-wild-type protein antiserum. Thus they need not necessarily be 'CRMs'.

CHARACTERIZATION OF A TRANSFER FACTOR ASSOCIATED WITH DRUG RESISTANCE IN *Salmonella typhimurium*

By DR. E. S. ANDERSON and DR. M. J. LEWIS

Enteric Reference Laboratory, Public Health Laboratory Service, Colindale Avenue, London, N.W.9

IN a previous article¹ we reported the results of an investigation of multiple drug resistance in phage-type 29 of *Salmonella typhimurium*. This type has become predominant in bovine infection in Britain, and has caused many human infections which are almost certainly bovine in origin. We believe that its prevalence in cattle is due to a combination of two major factors: low standards of hygiene in intensive farming, in cattle markets, and in the transport of animals on the one hand; and on the other the widespread use in animal husbandry of antibiotics and synthetic anti-bacterial drugs. The first factor predisposes to the spread of infection in calves, a spread amplified by the distribution of infected animals by dealers; the second ensures the emergence and maintenance of drug-resistant strains of *S. typhimurium*. This article presents a more detailed analysis of drug-resistance in phage-type 29 and discusses the significance of our findings both in relation to the systems we have examined, and to drug resistance transfer in general in the Enterobacteriaceae.

We shall use the same notation for resistance to the various drugs as in our earlier report¹. This is: *A*, ampicillin; *S*, streptomycin; *Su*, sulphonamides; and *T*, tetracycline.

Our previous observations may be summarized as follows: phage-type 29 had apparently acquired its drug resistance in the following order: streptomycin and sulphonamides (these seem to be linked); tetracycline; ampicillin. Attention was concentrated principally on strains showing this complete pattern of resistance, which was originally designated *A S T Su*. The level of resistance to all these drugs was higher than that found earlier in phage-type 1a of *S. typhimurium*², which had an identical spectrum of resistance. Moreover, it was found

that each component of the spectrum in type 29 (assuming *S Su* to be single) was transferred independently in crosses with *Escherichia coli* K12F⁻, in contrast to type 1a, in which the complete resistance pattern was transferred simultaneously. When ampicillin resistance was lost spontaneously in type 29, resistance to streptomycin, sulphonamides and tetracycline was retained. This again differed from the behaviour of type 1a, where loss of ampicillin resistance was accompanied by loss of resistance to all the other drugs. The transferable resistance factors (*R*-factors) of type 29 were designated *A'*, *S'* and *T'*. Their frequencies of transfer from type 29 to K12 in mating mixtures incubated for 24 h were approximately: *A'* 2×10^{-2} , *S'* 10^{-2} , *T'* 2×10^{-6} . Joint transfer of *A'* and *S'* took place at a frequency of 2×10^{-3} , which is a log unit higher than would be expected if these factors were completely independent. *T'* was not transferred jointly with *A'* or *S'*, nor was joint transfer of all three factors encountered. *S'*, *T'* and *A'* were sequentially transferred into a drug-sensitive strain of type 29 from K12 clones to which the single factors had originally been transferred from the wild resistant strain of type 29. In this way the *A' S' T'* resistance spectrum of type 29 was 'synthesized' artificially, and the possibility of step-wise acquisition of resistance in the wild state was confirmed.

R-factors are postulated to consist of two components: the genetic fragment determining the specific drug resistance, designated the resistance determinant (*R*-determinant); and the resistance transfer factor (*RTF*), the episome which confers autonomy on the complex and mediates the conjugation resulting in transfer. During transfer the *R*-determinant and the *RTF* move jointly, and infectivity of the resistance is maintained. The *R*-factor replicates independently of, and faster than, the

bacterial chromosome and it is believed that several copies of it exist in each infected cell.

In extending our investigation we considered the possibility that in nature, in the animal intestine, for example, *R*-factors might be passing continuously between Enterobacteriaceae. Thus, *Salmonellae* might acquire *R*-factors from *E. coli* and might transfer them to other *E. coli*, which might then pass them to other *Salmonellae* or to other *E. coli*, and so on. In other words, we thought of the possibility of 'cycles' of transfer of resistance, and we decided, using *S. typhimurium* of several phage-types and *E. coli* K12^F— as the bacterial hosts, to examine the results of repeated 'cycling' of the *R*-factors *A'*, *S'* and *T'* between these hosts, in order to determine what information could be gained about the operation of *R*-factors by this procedure.

The following notation has been devised to describe the characters of the strains. The description starts with the designation of the strain, that is, the phage-type in the case of *S. typhimurium*, K12 in the case of *E. coli* K12^F—. This is followed by the symbol of the drug resistance, for example, *A'* for high resistance to ampicillin. Cycles of transfer are designated in steps of 0.5 and the respective stage is marked as a subscript to the resistance symbol. The wild donor strain is regarded as zero in the series of transfer cycles, so that, for example, ampicillin resistance transferred from wild resistant type 29 to K12 appears in the K12 progeny as *A'*_{0.5}. Thus, K12*A'*_{0.5} is K12 which has received *A'* from the wild type 29*A'S'T'*; and type 29*A'*_{1.0} is wild sensitive type 29 that has received *A'* from K12*A'*_{0.5}. K12*A'*_{1.5} has received *A'* from type 29*A'*_{1.0}; and type 29*A'*_{2.0} has in turn received *A'* from K12*A'*_{1.5}; and so on. In some instances individual *R*-factors in a single clone represent different transfer cycles, and this is indicated. For instance, K12*A'S'*_{0.5} would be K12 that had received *A'* direct from the wild resistant type 29 and *S'* from type 29*S'*_{1.0}. When *R*-factors are transferred jointly in a cross, the cycle number is placed at the end of their designation only. Thus, K12*A'S'*_{0.5} indicates the joint transfer of ampicillin and streptomycin-sulphonamide resistance to K12 from wild resistant type 29.

Liquid medium (Difco broth) for the growth of cultures and mating mixtures contained 20 g of Bacto dehydrated nutrient broth (Difco Laboratories) and 8.5 g of sodium chloride/l. Solid medium for the routine growth of cultures contained 13 g of New Zealand powdered agar per litre of Difco broth. 'Bacto' MacConkey agar (Difco Laboratories) was used throughout to differentiate between *S. typhimurium* and K12 in mating mixtures.

We effected great technical economy in examining the results of crosses by streaking successive dilutions of mating mixtures with a standard loop delivering a volume close to 0.01 ml. This enabled us to inoculate the complete series of dilutions, 10⁰ to 10⁻⁷, in parallel streaks on two plates, the first with 10⁰ to 10⁻³, the second with 10⁻⁴ to 10⁻⁷. Each plate was streaked in duplicate and the results used were the mean of the two plates. This method is not so statistically accurate as using separate spread plates and larger volumes for each dilution, but it indicates orders of magnitude of transfer frequencies with acceptable precision to about 10⁻⁷, is reproducible, and the results were found to agree closely with those in which separate spread plates were used for each dilution.

When the donor strain was *S. typhimurium* it was eliminated from the mating mixture with phage 01 (refs. 1 and 4), and this phage was used for the same purpose in interrupted mating experiments. When the donor was K12 it was eliminated with colicine *E*2, which reduces K12 to about 10⁻⁵ to 10⁻⁶ of its original count. For this elimination of donor cells, 0.3 ml. of phage 01 (titre > 10¹¹ particles/ml.) or of colicine *E*2 (titre 1:32), as required, was spread on the MacConkey plates before they were streaked with the mating mixtures.

With the exception of interrupted mating experiments, crosses were carried out by mixing donor and recipient

cultures grown for 6–8 h at 37° C with agitation, incubating overnight, and streaking decimal dilutions of the mixture on MacConkey medium containing the respective anti-bacterial drugs in the concentrations previously specified¹ on the following day. Controls were always included of the separate cultures tested on the anti-bacterial drugs and inoculated with phage 01 or colicine *E*2, as appropriate. The separate donor and recipient cultures and the mating mixtures were also plated on MacConkey medium devoid of drugs; these plates were designated 'unselected' because of the absence of drugs, and were of great value in later experiments.

Transfer frequencies were calculated in terms of the final total count of the recipient strain in the mating mixture.

The controls of sensitive recipient strains on medium containing drugs gave the same result throughout, that is, no resistant colonies were found.

The first cross in the present series was type 29*A'*_{1.0}*S'*_{1.0}*T'*_{1.0} × K12. The results of this cross are shown in Table 1, together with those of the cross of wild type 29*A'S'T'* × K12 (see ref. 1).

Table 1. COMPARISON OF CROSSES OF WILD-TYPE 29*A'S'T'* × K12 AND TYPE 29*A'*_{1.0}*S'*_{1.0}*T'*_{1.0} × K12

Donor × recipient	Progeny	Frequency
29 <i>A'S'T'</i> × K12	K12 <i>A'</i> _{0.5}	2.5 × 10 ⁻³
	K12 <i>S'</i> _{0.5}	1.0 × 10 ⁻³
	K12 <i>A'S'</i> _{0.5}	2.0 × 10 ⁻³
	K12 <i>T'</i> _{0.5}	2.0 × 10 ⁻⁴
	K12 <i>A'S'T'</i> _{0.5}	2.0 × 10 ⁻³
29 <i>A'</i> _{1.0} <i>S'</i> _{1.0} <i>T'</i> _{1.0} × K12	K12 <i>A'</i> _{1.5}	5.0 × 10 ⁻³
	K12 <i>A'S'</i> _{1.5}	7.0 × 10 ⁻⁴
	K12 <i>T'</i> _{1.5}	4.0 × 10 ⁻⁴
	K12 <i>A'S'T'</i> _{1.5}	4.0 × 10 ⁻⁴

K12, *Escherichia coli* K12^F—

Type 29, *Salmonella typhimurium* phage-type 29.

29*A'S'T'*, wild resistant type 29.

29*A'*_{1.0}*S'*_{1.0}*T'*_{1.0}, type 29 into which the *R*-factors were introduced in three separate steps from K12*A'*_{0.5}, K12*S'*_{0.5} and K12*T'*_{0.5}, respectively.

Several interesting features are apparent in Table 1. The most striking is the increase in the frequency of transfer of *T'* from 2.0 × 10⁻⁶ in the 0.5 cycle to 4.0 × 10⁻⁴ in the 1.5 cycle. The second is the high degree of association apparent in the 1.5 cycle between *A'* and *T'* on one hand and *S'* and *T'* on the other, an association absent in the 0.5 cycle. The third is the frequency of 7.0 × 10⁻⁴ of joint transfer of all three resistances in the 1.5 cycle, in contrast to the complete absence of this class in the 0.5 cycle. However, if we ignore *T'* transfer, it is apparent that the transfer frequency of *A'* and *S'* alone or together is about the same in the 1.5 cycle as it was in the 0.5 cycle.

In order to distinguish between the efficiently moving tetracycline *R*-factor demonstrated in the 1.5 cycle and the much slower-moving tetracycline *R*-factor in the wild type 29*A'S'T'*, we designated the more rapidly moving factor *T''*, in contrast to *T'* found in the wild strain. The two factors conferred the same degree of tetracycline resistance, that is, the minimal inhibitory concentration of the drug in liquid medium was 250 µg/ml. with *S. typhimurium*, and 125 µg/ml. with K12. The symbol *T''* will now be used from K12*T''*_{0.5} onwards.

Bearing in mind the high rate of transfer of *T''* alone (4.0 × 10⁻⁴), it might be thought that the explanation for its presence in most cells receiving *A'* or *S'* or *A'S'* is that a high proportion of cells finally containing *A'* or *S'* would receive *T''*, even if the latter were unlinked to *A'* or *S'*. This hypothesis was tested by carrying out a cross of type 29*A'*_{1.0}*S'*_{1.0}*T''*_{1.0} × K12, interrupted from zero time onwards. The results of this experiment, which will be given in detail later, showed that the total frequency of transfer of *A'* at zero time was 10⁻⁴, that the majority of colonies selected on penicillin were of the type *A'T''*, but that about 10 per cent were pure *A'* colonies. Similarly, *S'*, which usually transfers more slowly than *A'* (ref. 1), appeared alone in about 10 per cent of colonies selected on streptomycin at 60 min. Pure *A'* and *S'* colonies were isolated up to 4 h after mixing donor and recipient cultures, but were no longer found among colonies selected (46 in each case) on penicillin and streptomycin plates after mating was continued for a further 20 h. The classes

then identified on penicillin selection were: $A'T''$ (46/46); and on streptomycin selection $S'T''$ and $A'S'T''$ (39/46 and 7/46 respectively).

It is thus apparent that the association between T'' on the one hand and A' or S' on the other is present from zero time, which leads to the conclusion that it is due to linkage between T'' and A' , or S' , in the 1.5 cycle, a linkage absent in the 0.5 cycle. Because of the transfer of the three R -factors alone, however, this experiment also indicates either that each factor segregates frequently from linkage with the other two, or that each exists independently as well as in combination in the donor strain $29A'_{1.0}S'_{1.0}T''_{1.0}$. If the latter suggestion is correct, the possible independent R -factor groupings available for transfer in this donor strain then become: A' ; S' ; T'' ; $A'S'$; $A'T''$; $S'T''$ and $A'S'T''$. Of these, only the class $A'S'$ was not identified in the recipient strain of K12 in this experiment, although it has been found in the progeny of later crosses.

The transfer of A' , including classes in which it was transferred jointly with T'' , or with S' and T'' , was 10^{-4} at zero time and reached 2.0×10^{-3} in 2 h; it remained unchanged between 2 and 4 h, and did not greatly increase after overnight contact. Pure T'' transfer reached a frequency similar to that of A' after 2 h, but greatly increased overnight to attain a figure close to unity. Although $A'T''$ transfer predominated over that of A' at zero time, its relative frequency increased between 4 and 24 h. Similar observations to those with A' and $A'T''$ were made with S' and $S'T''$, where a relative increase in frequency of the $S'T''$ class was also apparent between 4 and 24 h.

The next cross was $K12A'S'T''_{1.5} \times$ wild sensitive type 29, which is shown in Table 2.

Table 2. CROSS OF $K12A'S'T''_{1.5} \times$ WILD SENSITIVE TYPE 29

Selected on	No. tested	Progeny (all type 29) (2.0 cycle)	Frequency
P (penicillin)	20	19 $A'T''$ 1 $A'S'T''$	10^{-2}
S (streptomycin)	20	15 $S'T''$ 5 $A'S'T''$	7.0×10^{-3}
T (tetracycline)	20	All T''	7.6×10^{-1}
PS	20	All $A'S'T''$	1.1×10^{-2}
PT	20	19 $A'T''$ 1 $A'S'T''$	1.2×10^{-2}
ST	20	14 $S'T''$ 6 $A'S'T''$	8.0×10^{-3}
PST	20	All $A'S'T''$	1.3×10^{-2}
Unselected	50	31 T'' 1 $A'T''$ 18 sensitive	6.2×10^{-1} 2×10^{-2}

It can be seen from Table 2 that the results of this cross (2.0 cycle) are qualitatively similar to those of the 1.5 cycle of type 29 \times K12 (Table 1) that is, that there is a high degree of linkage between T'' on the one hand and A' or S' on the other, and the T'' transfer frequency is very high at c. 7.0×10^{-1} .

An interrupted mating experiment with the same donor and recipient strains established that recipients of the classes $29A'_{2.0}$ and $29S'_{2.0}$ were detectable at early stages of the cross, but that linkage of A' and S' with T'' again predominated. An unexpected finding was that, in the progeny of this cross, the class $29A'_{2.0}$ would not transfer A' to K12, although four lines of $29A'_{2.0}$ were tested for this transfer. Superficially, then, $29A'_{2.0}$ is indistinguishable from a drug-resistant mutant. It retains its high ampicillin resistance and produces abundant β -lactamase. The natural conclusion is that $29A'_{2.0}$ cells do not carry the RTF , but the question then to be solved is whether the A' determinant has become integrated into the bacterial chromosome or whether it is cytoplasmic but autonomous. In exploring this phenomenon further, we tested $K12A'_{1.5}$ (Table 1) to find that this was also unable to transfer to type 29. Bearing in mind that the cross $K12A'S'T''_{1.5} \times$ type 29 yielded the class $29A'_{2.0}$, and also that all cycles after 1.0 showed a high degree of association between T'' and A' , it seemed probable that if we transferred T'' into the 'infertile' $29A'_{2.0}$, the A' R -determinant would be

re-mobilized. This expectation was fulfilled, as Table 3 shows.

Table 3. MOBILIZATION OF $A'_{1.0}$ IN TYPE 29 WITH T'' FROM $K12T''$

Cross Donor \times recipient	Selected on	Progeny	Frequency
$29A'_{1.0} \times K12$	P	—	$< 10^{-7}$
$K12T''_{0.5} \times 29A'_{1.0}$	T	$29A'_{1.0}T''_{1.0}$	2×10^{-1}
$29A'_{1.0}T''_{1.0} \times K12$	P	$K12A'T''_{1.0}$ $K12T''$	10^{-2} $\sim 10^0$

It is evident that, once mobilized by T'' , the A' determinant was transferred to K12 with the frequency it has maintained from our first experiments, that is, about 10^{-2} . In transfer of the mobilized A' into K12, only the class $A'T''$ was identified, but preceding experiments show that this is to be expected since, in overnight crosses with $A'T''$ donors, the A' class is easily detectable only at an early stage of conjugation. It may be concluded from this experiment that, although the introduction of T'' results in the restoration of the transferability of A' , the rate of A' transfer is independent of T'' and is probably a function of the complex formed by A' and the RTF . The mobilizing activity of T'' may thus be due to a close association with the RTF , and the high frequency of coincidental transfer of T'' with A' would be an expression of this association. When T'' and A' are transferred simultaneously, therefore, it is unnecessary to postulate a linkage between them other than their attachment to the same RTF unit.

An examination of S' yielded similar results, although it was found that the loss of the RTF by S' occurred earlier than with A' , since three out of four lines of $29S'_{1.0}$ tested would not transfer S' to K12. Table 4 shows the mobilization of S' by T'' in type $29S'_{1.0}$.

Table 4. MOBILIZATION OF $S'_{1.0}$ IN TYPE 29 WITH T'' FROM $K12T''_{0.5}$

Cross Donor \times recipient	Selected on	Progeny	Frequency
$29S'_{1.0} \times K12$	S	—	$< 10^{-7}$
$K12T''_{0.5} \times 29S'_{1.0}$	T	$29S'_{1.0}T''_{1.0}$	5×10^{-1}
$29S'_{1.0}T''_{1.0} \times K12$	S	$K12S'T''_{1.0}$ $K12S'T''_{1.0}$	10^{-3}
	T	$K12T''_{1.0}$	7.0×10^{-1}

Although the $S'T''$ class predominated in recipient colonies selected on streptomycin, S' alone was detected in a small minority of colonies. The total transfer frequency of S' (including lines in which it was jointly transferred with T'') to K12 was 10^{-2} , slightly lower than that observed in transfer from wild type $29A'S'T''$ to K12. As with A' transfer, it can be concluded that the transfer rate of S' is characteristic of the $S'-RTF$ attachment and is independent of T'' , which appears with S' only because of its coincidental attachment to the same RTF unit.

At this point we introduced type 14 of *S. typhimurium* into the investigation. This type is commonly associated with avian infection, while type 29 is at present predominantly bovine. As drug resistance in *S. typhimurium* is apparently less of a problem in fowls than in cattle, we thought it worthwhile to determine whether type 14 was less able to pick up and to transfer resistance than was type 29. $K12A'S'T''_{1.5}$ (Table 1) was chosen as the donor in the first cross with type 14. The resulting *S. typhimurium* progeny were tested for drug resistance and transfer, and were phage-typed. An analysis of our findings in these experiments is given in Table 5.

Several conclusions may be drawn from a study of Table 5. First, it is evident that transfer of resistance takes place into and out of type 14, so that complete 'infertility' is not the reason for the low incidence of drug resistance in this type. Second, the transfer of T'' to type 14 shows a much lower frequency than that encountered when the same donor is crossed with type 29, indicating that different strains may vary in their efficiency as recipients of R -factors. Third, the patterns of transfer conform to those already found in type 29 (the absence of the class $14S'_{2.0}$ is due to the examination of insufficient colonies from the selection on streptomycin). Fourth, in most instances the acquisition of resistance was accompanied by a change of phage-type; the resulting type

Table 5. TRANSFER OF DRUG RESISTANCE INTO AND FROM *S. typhimurium* PHAGE-TYPE 14

Cross	Donor × recipient	Progeny	Frequency	Phage-type
K12 A'ST _{1.5} × 14		14 A' _{0.5}	5 × 10 ⁻⁴	14*
		14 A'T _{0.5}		29
		14 A'ST _{0.5}		29
		14 S'T _{0.5}		29
K12 A' _{0.5} × 14		14 A' _{1.0}	3 × 10 ⁻³	29
		14 T _{0.5}		29
K12 T _{0.5} × 14		14 A' _{1.0}	3 × 10 ⁻³	29
		14 T _{1.0}		29
14 A'T _{0.5} × K12		Unselected (50 colonies)	All sensitive	1 = 29
		K12 A'T _{0.5}	to T	49 = 14
		K12 T _{0.5}	6 × 10 ⁻¹	—

* One colony only, unable to transfer A'.

is designated '29' because, although its phage-typing reaction is closer to 29 than to any other type, it is nevertheless distinguishable from 29. Fifth, this change of phage-type was the same, irrespective of the resistance acquired. Sixth, the frequency of transfer of A' from K12A'_{0.5} to 14 was effectively the same as the total frequency of transfer of the A' factor (including the classes in which it was transferred simultaneously with T'' and S') in the cross K12A'S'T''_{1.5} × 14. Seventh, one line presented ampicillin resistance without change of phage-type. Eighth, a colony, picked without selection, from the cross K12T''_{0.5} × 14 showed a change of phage-type without the acquisition of tetracycline resistance.

Type 14 is unable to produce the type 1 or type 2 fimbriae found in salmonellae⁶ and the strain we used in these experiments is predominantly non-flagellate. The absence of fimbriae and flagella should facilitate the detection of new surface structures, and we are currently investigating the possibility that type 14 may provide a means of detecting the structures responsible for conjugation in resistance transfer.

The transfer investigations on type 14 showed the need for a notation which would indicate when necessary whether a strain of *S. typhimurium* had changed its phage-type on being crossed with a drug-resistant donor, and whether the change of phage-type was accompanied by transfer of resistance. Using type 14 as our model, the system adopted was to indicate, from left to right, the original phage-type, the R-determinant and its cycle number, followed by the final phage-type in brackets. Thus, 14A'T''_{2.0}(29) is type 14 that has acquired resistance to ampicillin and tetracycline jointly in a second cycle cross and has changed its phage-type to '29'. In contrast, 14A'_{2.0}(14) has received ampicillin resistance but has not changed its phage-type. And 14(29) has changed its phage-type without acquiring resistance.

Changes in phage-type can have only a limited expression in type 14, because its sensitivity to the *S. typhimurium* typing phages is already restricted. A better host from this point of view is type 36, which is sensitive to all of the 30 typing phages and in which changes in phage sensitivity are thus easy to detect. Mating experiments were, therefore, carried out with this type and K12. These are summarized in Table 6.

As Table 6 shows, all the R-factors can be transferred to type 36. The frequency of transfer of A' from K12A'_{0.5} to 36 is closely similar to that of the sum of A'T'' and A'S'T'' from K12A'S'T''_{1.5} to 36, and can be taken in both cases as a measure of the transfer of A', as we have already suggested. The class A'S'T''_{2.0} measures the joint transfer of A' and S'. This is confirmed by the results of the cross of K12A'S'_{0.5} × 36 (not included in Table 6), in which A' was transferred at 2.5 × 10⁻⁴, S' at 1.5 × 10⁻⁴ and A'S' at 2.5 × 10⁻⁵. T'' alone, as Table 6 shows, was transferred with high frequency to type 36, both from K12T''_{0.5} and from K12A'S'T''_{1.5}, that is, 3.0 × 10⁻¹ and 2 × 10⁻¹ respectively. This is close to the frequency of transfer of the same factor to type 29 and K12, and much higher than that to type 14, which is 3.0 × 10⁻³.

In most cases transfer of resistance caused the recipient strain of *S. typhimurium* to change its phage-type from 36, which is sensitive to all 30 of the typing phages, to type 6, which is sensitive to only 9 of the phages. This change

was irrespective of the R-factor received. However, the classes 36A'(36) and 36S'(36) were also isolated. In addition, tests of unselected colonies in the crosses K12A'_{0.5} × 36 and K12S'_{0.5} × 36 resulted in the isolation of a number of colonies of *S. typhimurium* that had changed their phage-type to 6 without receiving drug resistance.

Table 6. TRANSFER OF DRUG RESISTANCE INTO AND FROM *S. typhimurium* PHAGE-TYPE 36

Donor × recipient	Selected on	Progeny	Frequency	No. phage-typed	Phage-type
K12 A' _{0.5} × 36	P	A' _{1.0}	4 × 10 ⁻⁴	6	5 = type 6 1 = type 36
	Unselected	All sensitive to P	—	4	2 = type 6 2 = type 36
K12 S' _{0.5} × 36	S	S' _{1.0}	3 × 10 ⁻⁴	9	All type 6
	Unselected	All sensitive to S	—	10	3 = type 6 7 = type 36
K12 T'' _{0.5} × 36	T	T'' _{1.0}	3 × 10 ⁻¹	10	All type 6
	Unselected (10 colonies picked)	9 sensitive to T''	—	10	9 = type 36 1 = type 6
K12 A'S'T'' _{1.5} × 36	P (50 picked)	47 A'T'' _{0.5}	2 × 10 ⁻⁴	50	All type 6
		3 A'S'T'' _{0.5}		50	1 = type 36
	S (50 picked)	42 S'T'' _{0.5}	5 × 10 ⁻⁵	42	7 = type 6
		7 A'S'T'' _{0.5}		—	—
	T (50 picked)	All T'' _{0.5}	2 × 10 ⁻¹	50	All type 6
		12 T'' _{0.5}		—	12 = type 6
K12 × 36	Unselected	38 sensitive to P, S and T	—	50	38 = type 36
	Unselected	—	—	200	All type 36
				100	All type 36

It was found that those lines of 36 into which the transfer of A' and S' had caused a change of phage-type would transfer their drug resistance to K12 with the usual frequencies, 2.4 × 10⁻² for A' and 2.0 × 10⁻² for S'. In contrast, lines that had acquired A' or S' without a change of phage-type were unable to transfer their resistance to K12. We also had a line of type 14 that had acquired ampicillin resistance without changing its phage-type (see Table 5) and this could not transfer its resistance to K12, while type 14 that had received this resistance accompanied by a change of phage-type to '29' could do so. Moreover, there was a line of type 14 that had changed to '29' but had not acquired drug resistance (Table 5). It seemed probable that lines which had received drug-resistance and had changed in phage-type and would transfer resistance had acquired both the R-determinant and the RTF; that those which had received resistance but had not changed in phage-type and would not transfer, had received the R-determinant but not the RTF; and that those which had changed in phage-type but had not received resistance had received the RTF but not the R-determinant, that is, that the RTF was responsible for the characteristic change of phage-type in the host cells of *S. typhimurium*. Furthermore, because of the uniformity of the change of type, only one RTF seemed to be implicated in the transfer system we were studying. It was also evident that the RTF could move independently of the R-determinant-RTF complexes and it was probable that the lines of *S. typhimurium* in which we believed the RTF alone to be present would transfer it to 'uninfected' strains and to strains carrying R-determinants only, in the latter case restoring the integrity of the R-factors and the ability to transfer. We have provisionally assigned the Greek letter Δ to the RTF present in this system.

A complete R-factor should be designated by the symbol of the drug resistance plus that of the RTF, and this will now be included where necessary. Thus, 36S'Δ+(6) is a line of type 36 that has received the R-determinant S' and the RTF, has changed its phage-type to 6, and will transfer S'; 36S'Δ-(36) has received the R-determinant but not the RTF, has not changed its phage-type, and will not transfer S'; and 36Δ+(6) has received the RTF but not the R-determinant, has changed its phage-type, and will transfer Δ.

Table 7 summarizes experiments aimed at demonstrating the transferability of Δ and its mobilization of

R-determinants believed to have lost the transfer property because of the absence of Δ . When Δ alone is transferred into a recipient strain an asterisk is added.

Table 7. TESTS OF INDEPENDENT MOBILITY OF THE *RTF Δ* AND OF ITS ACTIVATION OF RESISTANCE TRANSFER

Cross No.	Donor \times recipient	Progeny	Frequency
I	36 <i>S'</i> Δ + (6) \times K12	K12 <i>S'</i>	3×10^{-3}
II	36 <i>S'</i> Δ - (36) \times K12	—	$< 10^{-7}$
III	36 Δ + (6) \times 36 <i>S'</i> Δ - (36)	36 <i>S'</i> Δ * (6)	3.6×10^{-1}
IV	36 <i>S'</i> Δ * (6) \times K12	K12 <i>S'</i>	10^{-2}
V	14 <i>A'</i> Δ + (20) \times K12	K12 <i>A'</i>	1.3×10^{-3}
VI	14 <i>A'</i> Δ - (14) \times K12	—	$< 10^{-7}$
VII	36 Δ + (6) \times 36 <i>S'</i> Δ - (36) \times K12	K12 <i>S'</i>	4×10^{-5}
VIII	36 Δ + (6) \times 14 <i>A'</i> Δ - (14) \times K12	K12 <i>A'</i>	10^{-4}

* Indicates the transfer of Δ alone.

Crosses I and V demonstrated that *S. typhimurium* that had initially received a complete *R*-factor (that is, the *R*-determinant plus Δ), and had changed in phage-type, would transfer resistance to K12; crosses II and VI confirmed that *S. typhimurium* strains which had received the *R*-determinant but not Δ and had not changed in phage type, would not transfer; cross III showed the transfer of Δ from 36 Δ + (6) into 36 *S'* Δ - (36), with resultant change of phage-type; and cross IV confirmed that the transfer of Δ into the Δ - strain of type 36 had, in addition to changing its phage-type, endowed it with the ability to transfer *S'* to K12. Cross VII, in which 36 *S'* Δ - (36) was used as the intermediate and K12 as the final recipient, was carried out to determine whether the two-stage transfers incorporated in crosses III and IV could be combined in a single experiment, and this proved to be so, although the frequency of transfer of *S'* to K12 was much lower than when the experiment was performed in separate stages. Having established that this type of cross was successful, the method was applied to the mobilization of *A'* in type 14 *A'* Δ - (14), as cross VIII shows.

A striking feature of cross III is the high frequency of transfer of Δ , 3.6×10^{-1} , into *S. typhimurium* type 36 lacking it. This frequency is the same as that of the transfer of *T''* from K12 into sensitive type 29 (Table 3) and into type 36. The significance of this will be discussed later.

These experiments confirm that Δ , or a factor associated with Δ , is responsible for the characteristic change in phage-type in *S. typhimurium*; that drug-resistant strains lacking Δ will not transfer their resistance; and that when Δ is introduced into such strains it unites with the *R*-determinant to form the *R*-factor, which can then be transferred.

It is thus clear that Δ alone may exist in Enterobacteriaceae, and that it is highly communicable in its 'free' state. Although we have so far identified only the properties of communicability, ability to change the phage-type of *S. typhimurium* in a defined fashion, and mobilization of non-transferring *R*-determinants, it may have other genetic properties that we have not yet recognized.

We have prepared lines of K12 containing Δ alone, that is, K12 Δ +, by crossing 36 Δ + with K12 *F* -. A number of K12 colonies were picked without selection from this cross and ten of these were tested individually by incorporation in mating mixtures containing both type 36 *S'* Δ - and K12. Transfer of streptomycin resistance to K12 in these crosses could occur only by the infection of 36 *S'* Δ - with Δ from K12 Δ + to produce 36 *S'* Δ +, which could then transfer *S'* to K12. Nine of the ten colonies tested proved to be K12 Δ +. The mobilization of *R*-determinants in this way may be a useful method of detecting the presence of transfer factors in drug-sensitive strains of Enterobacteriaceae.

One of the K12 Δ + colonies was crossed with type 36, and 50 colonies of the recipient strain picked without selection and phage-typed. Sixteen belonged to phage-type 6, representing a Δ transfer frequency of 3.2×10^{-1} .

Having established the role of Δ in the transfer of drug resistance in the systems we have studied, the possibility

that it might be able to mediate the transfer of other properties was investigated. It is known that the *E2* colicinogenic factor (col *E2*) cannot be transferred from strains carrying it unless the I colicinogenic factor (col I) is first introduced into them⁶. It seemed possible that we were dealing with an analogous situation in the mobilization of the *A'* and *S'* resistance-determinants by the *T''* *R*-factor, and that the I colicinogenic determinant was active in col *E2* transfer only because of its attachment to a transfer factor, in the same way as the mobilizing activity of *T''* is due to the presence of Δ . We therefore investigated the possibility that Δ might mediate col *E2* transfer. The *T''* *R*-factor was used as a marker of Δ transfer in this experiment. It was transferred from K12 *T''* -₅ into a strain of *S. typhimurium* LT2 colicinogenic for *E2* but unable to transfer *E2* colicinogeny to K12. A tetracycline-resistant colony of LT2 (col *E2*) resulting from this cross was then mated with K12. Colicinogeny was detected by inoculating selected colonies in a premarked pattern on a Difco agar plate already flooded with the indicator strain, which was K12 *F* -. Zones of colicinogeny were clearly apparent after 8 h incubation at 37° C.

These experiments are summarized in Table 8.

Table 8. MOBILIZATION OF COLICINOGENIC FACTOR *E2* WITH *R*-FACTOR *T''*

Cross	Selected on	Progeny	Frequency
K12 <i>T''</i> \times LT2 (col <i>E2</i>)	<i>T</i>	LT2 <i>T''</i> (col <i>E2</i>)	5×10^{-1}
LT2 <i>T''</i> (col <i>E2</i>) \times K12	<i>T</i>	K12 <i>T''</i> (col <i>E2</i>)	$\sim 10^{-4}$
LT2 (col <i>E2</i>) \times K12	Unselected	—	$< 10^{-6}$

The second cross in Table 8 shows the transfer of col *E2* into K12, using the *R*-factor *T''* as the vector. The frequency of col *E2* transfer was about 10^{-4} per LT2 donor cell. The third cross is a control which shows that without the mediation of *T''* this transfer will not take place.

One of the K12 *T''* (col *E2*) progeny from this experiment was then crossed with type 36. The result is given in Table 9.

Table 9. TRANSFER OF *T''* AND *E2* COLICINOGENY FROM K12 TO TYPE 36

Cross	Selected on	No. picked	Progeny	Frequency
K12 <i>T''</i> (col <i>E2</i>) \times 36	<i>T</i>	50	5 <i>T''</i> (col <i>E2</i>)	7×10^{-2}
			45 <i>T''</i>	6.3×10^{-1}
	Unselected	50	3 <i>T''</i> (col <i>E2</i>)	6×10^{-2}
			23 <i>T''</i>	4.6×10^{-1}
			24 sensitive and col -	

All *S. typhimurium* progeny carrying *T''* or *T''* (col *E2*) had changed from phage-type 36 into phage-type 3.

The results of this cross are analogous to those with donors carrying *A'* and *T''*, or *S'* and *T''*, that is, col *E2* shows a high degree of association with *T''* in transfer, but *T''* alone transfers with much higher frequency. This suggests that in strains carrying *T''* and col *E2*, the *R*-determinant and the colicinogenic determinant are independently attached to Δ , but that, because of the close association of *T''* with Δ , the great majority of col *E2* determinants are attached to a Δ particle already carrying *T''* (the term particle is used for convenience only). This makes the detection of the class 36 (col *E2*) Δ + difficult. However, it can be predicted that if *A'* or *S'* were used to mobilize col *E2* in LT2 (col *E2*), transfer experiments into K12, and thence into type 36, would reveal the following *S. typhimurium* classes (in this example the *A'* resistance factor is used as the vector of Δ): 36 *A'* Δ +; 36 (col *E2*) Δ +; and 36 *A'* (col *E2*) Δ +. It should also be possible to demonstrate lines of both 36 *A'* and 36 (col *E2*) that were Δ -. Finally, about 59 per cent of the total *S. typhimurium* progeny would receive Δ alone.

Having demonstrated the mobilization of col *E2* by *T''*, it was obvious that the reverse test should be applied, that is, the mobilization of a non-transferring *R*-determinant by colicinogenic factor I. The experiments in which this was demonstrated are summarized in Table 10.

The appearance of K12 *S'* (col I) colonies in the first cross in Table 10 could result only from the transfer of the col I factor into 36 *S'* Δ -, which would then act as a donor of

Table 10. MOBILIZATION OF NON-TRANSFERRING S' BY COL I

Cross Donor \times recipient	Selected on	No. of colonies tested	Progeny	Frequency
LT2 (col I) \times 36 S' Δ - \times K12	S'	25	All K12 S' (col I)	10^{-3}
LT2 (col I) \times K12	Unselected	12	All K12 (col I)	$\sim 10^0$
K12 (col I) \times 36	Unselected	50	45 = 36 5 = 36 (col I)	10^{-1}
LT2 (col I)	Unselected	50	9 = 36 S' (col I) Δ - 41 = 36 S' Δ -	2×10^{-1}
\times 36 S' Δ -	S'	50	All K12 S' (col I)	10^{-2}
36 S' (col I) Δ -	Unselected	40	1 K12 S' (col I) 39 K12 (col I)	$\sim 2.0 \times 10^{-2}$ 9.8×10^{-1}
\times K12				

the S' (col I) complex to K12. It is apparent from Table 10 that col I is as effective in mobilizing S' as is T'' (Table 5), and its activity in this respect must be due to its association with a transfer factor. The high frequency of transfer of col I to both K12 and *S. typhimurium*, and the fact that an obvious majority of K12 cells receiving S' from 36 S' (col I) Δ - also received col I, suggest that the colicinogenic determinant is firmly attached to its transfer factor in the same way as the T'' determinant is attached to Δ , and that the col I transfer factor is highly communicable. Although this factor produces a detectable change of phage-type in type 36 of *S. typhimurium*, this is neither so clear-cut nor so extensive as that produced by Δ . Thus, the col I transfer factor is different from Δ . We have not so far isolated it in cells devoid of the determinant for colicine I synthesis but are endeavouring to do so.

In our earlier report we suggested that the A' , S' and T'' R -factors were independent of each other, with separate transfer frequencies from type 29 to K12 of about 2.0×10^{-2} , 10^{-2} and 2×10^{-6} respectively. The only finding inconsistent with this hypothesis was that the joint transfer of A' and S' was about a log unit higher than would be expected if these two R -factors were truly independent. Watanabe *et al.*⁷ observed a similar phenomenon in the joint transfer of f_1+ and f_1- R -factors, but we have so far no evidence of the existence of an RTF other than Δ , which seems to be f_1- , in the system on which we have concentrated. A further problem arose with the observation that T'' was transferred with frequencies approaching unity, whereas the transfer frequency of T' in the cross of wild type 29A' $S'T'' \times$ K12 was of the order of 10^{-6} . It was observed, moreover, that once T'' had appeared it showed a high degree of 'linkage' to A' and S' in all subsequent crosses, a feature absent from our initial crosses. The characteristic change of phage-type in *S. typhimurium* types 14 and 36 on receipt of R -factors, the absence of such changes in the same phage-types receiving non-transferring A' and S' , and the demonstration of a transferable factor which changed the phage-type of *S. typhimurium* without conferring resistance and which would mobilize non-transferring R -determinants, also required explanation.

We offer the following interpretations of these phenomena. In the original strain of *S. typhimurium* type 29A' $S'T''$ there were, in fact, only two R -factors, A' and S' . The tetracycline resistance was probably mutational, chromosomally located, and not associated with an RTF . The cross in which we observed the transfer of T' to K12 was thus a rare demonstration of the pick-up of the tetracycline-resistance gene from the chromosome by the RTF which we have designated Δ . T'' was transferred alone in this cross, which could be interpreted as an indication that there were free Δ particles in the host cell, or that T' was substituted for the A' or S' determinants in complete R -factors. Later experiments have inclined us to the view that a free Δ particle was concerned. Once effected, the attachment of T' to Δ has shown itself to be very stable; the R -factor, now T'' , thus shows a mobility closely similar to that of Δ , and the tetracycline R -determinant is rarely found in the absence of Δ , although, because of the persistence of free Δ particles, Δ may exceptionally be transferred without T'' (Table 6). The transferable agent changing the phage-type of *S. typhimurium* is Δ ,

the RTF ; crosses into *S. typhimurium* in which the R -determinant is transferred but Δ is lost, produce drug-resistant lines not showing the characteristic change of phage-type and unable to transfer their resistance. Such R -determinants may be integrated into the chromosome, but it seems more probable, because of the ease with which they are mobilized by Δ , that they are located in the cytoplasm. The transfer of T'' into lines of this type introduces Δ , to which the R -determinant, A' for example, becomes attached. This attachment is independent of that of T'' but, because of the close association of T'' with Δ , most copies of Δ will carry T'' , so that most Δ particles acquiring A' will already possess T'' and the resulting progeny will be of the type $A'T''$. When these cells are mated with a sensitive recipient they will transfer A' , $A'T''$ and T'' , but the A' class will be easily detectable early in the cross only.

Watanabe and Lyang⁸ also observed the mobilization of non-transferable R -determinants by a tetracycline R -factor, but offered in explanation the hypothesis that the initial loss of transferability was due to the RTF becoming 'defective', a fault repaired by the newly introduced tetracycline R -factor. We believe our explanation of this phenomenon to be more acceptable, and the identification of Δ as an infective agent producing a characteristic change of phage-type in *S. typhimurium*, apparently without transmitting drug-resistance, and independently capable of mobilizing non-transferring R -determinants, supports our hypothesis.

So far as we can judge, Δ seems to be the only RTF in this system. As R -determinants will transfer only when associated with Δ , the more frequent their association with it, the more frequently will they be transferred; that is, the frequency of transfer of a given R -determinant is governed by the number of R -determinant- Δ complexes available during the period of conjugation. A' transfers from *S. typhimurium* to K12 with slightly higher frequency than does S' , because A' is more frequently attached to Δ than is S' . The complexes $A'\Delta$ and $S'\Delta$ are independent and are dissociable; a high proportion of cells contain them in the dissociated state. Cells of this type transfer Δ only, and this has been shown to occur with a frequency approaching unity. (There are obvious similarities between this system and that of the F' factor in *E. coli* K12 (refs. 9, 10) that demand further exploration.) Cells containing the complete R -factors, $A'\Delta$ for example, probably transfer it alone. The tetracycline R -determinant is closely associated with Δ , which explains why its frequency of transfer approximates to that of Δ alone, why transfer of Δ only from $T''\Delta$ cells is unusual, and why non-transferring T'' is a rarity (we have not so far succeeded in identifying it).

The frequency of joint transfer of A' and S' might be due to independent transfer of the two R -factors to the same cells. However, on this hypothesis, the frequency of recipients showing joint transfer of A' and S' in our original experiments¹ should be about 2×10^{-4} , that is, the product of the individual frequencies of the two R -factors, whereas it was uniformly a log unit higher than expected. On the other hand, a small number of cells will contain A' and S' simultaneously attached to Δ , and these will therefore transfer both determinants together in the same way as A' and T'' are jointly transferred. This could raise the frequency of joint transfer of A' and S' beyond the level expected from independent transfers of the two R -factors, and it seems to us to be the most probable explanation of the discrepancy.

We have mentioned that, in crosses in which the classes A' and $A'T''$ or S' and $S'T''$ are transferred, the single R -factor classes A' and S' are usually detectable early in the cross only, and that there is a relative increase in the frequency of the double R -factor classes $A'T''$ or $S'T''$ late in the cross. We suggest that this is due to the fact that A' and S' tend to lose Δ during transfer, whereas T'' does not. The classes A' and S' , therefore, will spread to

only a limited extent between recipient cells once they have been transferred from the donor, while the classes $A'T''$ and $S'T''$ will continue to spread in the recipient culture because of the presence of T'' which acts as a vector of Δ . Moreover, recipient cells containing A' or S' only, without Δ , will be super-infected with T'' , which will produce a further increase in the $A'T''$ or $S'T''$ class.

It can be predicted that if the R -factor A' is used to introduce Δ into non-transferring S' in type 36 of *S. typhimurium*, and the resulting progeny, that is, $36A'S'\Delta+$, is then crossed with K12, the following classes of K12 should appear with approximately the following frequencies: A' , 2.0×10^{-2} ; S' , 10^{-2} ; $A'S'$, 10^{-3} . Table 11 shows the actual results of this experiment.

Table 11. MOBILIZATION OF $S'A-$ WITH $A'\Delta+$

Cross Donor \times recipient	Selected on	Progeny	Frequency
*36 $A'S'\Delta+$ \times K12	P	K12 A'	2.4×10^{-2}
	S	K12 S'	1.3×10^{-2}
	PS	K12 $A'S'$	3.0×10^{-3}

* A' and Δ had been introduced into type 36 $S'A-$ from K12 $A'\Delta+$.

Table 11 establishes the accuracy of the predictions. The experiment demonstrates that, once Δ is introduced into a cell carrying a non-transferring R -determinant, the frequency with which the resulting R -factor will transfer to other strains is that characteristic of the R -determinant- Δ complex, irrespective of whether the two elements are introduced together or separately. It also shows that, if Δ is introduced into such a cell in association with another R -determinant, the two resistances will manifest their usual frequencies of separate and joint transfer.

The frequency of transfer of R -factors may be postulated to depend on:

(1) *The recipient cell.* It is to be expected that different members of the Enterobacteriaceae will vary in their susceptibility to RTF infection. For example, type 14 of *S. typhimurium* is a poor recipient of T'' compared with types 29 and 36. A variability of transfer efficiency may also be found in different donor strains.

(2) *The rate of transmissibility of the RTF alone.* Under defined conditions this is evidently constant for each RTF .

(3) *The frequency or firmness of attachment of individual R -determinants to the RTF .* This is apparently constant for each R -determinant.

When a particular R -determinant has a firm attachment to the RTF , it will be transferred with a frequency approaching that of the RTF alone. It will also be transferred with high frequency simultaneously with other R -determinants which are attached to the same RTF . This will give the appearance of linkage between the two R -determinants concerned, but findings in the systems we have described suggest that this impression is probably illusory. Other R -determinants than T'' may exist which have a high frequency of attachment to an RTF . If a number of these are simultaneously attached to the same RTF they will usually be transferred together and this will suggest that the determinants themselves are closely linked. If the determinants were linked, however, the construction of the linkage group would demand that the respective drug-resistance genes, presumably occupying different chromosomal sites, should be picked up independently by the RTF and assembled into a linkage group, or that a cytoplasmic genetic element should exist which had mutational potentialities to confer resistance to a number of drugs. The hypothesis that the R -determinants themselves, whatever their origin, are independent of each other and attach independently to the RTF , seems to us a simpler conception. This argument is without prejudice to the possibility that some R -determinants may be small linkage groups conferring resistance to more than one drug. An example of this may be S' in type 29, which confers resistance to both streptomycin and sulphonamides. We have not so far been able to separate these two resistances.

The mediation of col $E2$ transfer by Δ , and of non-mobile S' transfer by the transfer factor of col I, establish that the transfer of genetic information other than that of drug resistance can be carried out by the resistance transfer factors, and of information other than that of colicinogeny by colicinogenic transfer factors. There seems to be no reason for supposing that such transfer does not take place in the wild state. The transfer of a single resistance with loss of the RTF , which we have demonstrated, results in the production of a line which, if isolated in the field, would be regarded as a drug-resistant mutant. This would apply to any character identified which could not be shown to be transmissible, and it raises the question of how many characters in the Enterobacteriaceae may owe their origin to transfers in which the transferring agent has been lost.

Iijima¹¹ reported mobilization of colicinogenic factor $E1$ with R factors. We have demonstrated the reciprocal transfer activities of Δ and the col I factor in relation to colicinogeny and drug resistance. It has also been shown that the F factor will mediate the transfer of tetracycline resistance¹² and that an RTF will potentiate recombination in $F-$ strains of K12 (ref. 13).

Watanabe³ pointed out operational analogies between the $RTFs$, the F factors and colicinogenic factor I (we have suggested that the transmissibility of the latter is due to a transfer factor and is probably independent of the colicinogeny determinant). The work we have described gives further support to the idea that the agents responsible for the transmission of genetic information in the Enterobacteriaceae by conjugation constitute a group of unknown size, showing remarkable catholicity in relation to the hosts they will "infect" and to the characters they will transfer.

We thank Mrs. B. E. Burford, Miss M. Burton, Mrs. L. Ward and Mr. F. J. Flynn for their assistance.

Note added in proof. Since this article was written, the technique of mobilization of a non-transferring R -determinant for the detection of transfer factors (TF) in drug-sensitive strains has been successfully applied to wild drug-sensitive strains of *S. typhimurium*. The wild strains were each incorporated in a mixture of type 36 $S'A-$ (intermediate recipient of the TF) and K12 (recipient of the transferable $S'-TF$ complex). Of 12 sensitive strains tested, 5 proved to be carrying transfer factors. Colicinogeny tests of the donor strains were negative. These transfer factors are now under investigation.

Yet another transfer factor has been identified in a strain of type 29 resistant to ampicillin, neomycin, streptomycin(-sulphonamides) and tetracycline. All resistances except that for tetracycline were easily transferable to K12; ampicillin and neomycin resistance at a frequency of about 5×10^{-1} , and streptomycin resistance at about 10^{-2} . Preliminary experiments suggest that the ampicillin R -determinant in this strain is the same as that in the type 29 strain in which the TF is Δ . If this is so, the high transfer frequency of ampicillin resistance in the new strain (5×10^{-1}) as compared with type 29 $A'S'T''$ (2×10^{-2}) indicates that the frequency of transfer of a given R -determinant depends on the transfer factor with which it is associated.

DIRECT AND INDIRECT EFFECTS OF RADIATION ON PLANT CELLS: THEIR RELATION TO GROWTH AND GROWTH INDUCTION

By DR. R. D. HOLSTEN, DR. M. SUGII and PROF. F. C. STEWARD, F.R.S.

Laboratory of Cell Physiology and Growth, Cornell University, Ithaca, New York

CONVENTIONAL interpretations of the biological effects of radiation are heavily committed to the direct consequences of the radiation on cells, particularly on their chromosomes. The genetic consequences of the radiation damage are interpreted in terms of the ability of the radiation to penetrate to the nucleus, to inactivate some particular part of the genetic apparatus and, by causing one or other of a variety of chromosomal aberrations, to affect not only that cell but also its lineal descendants.

Following this line of thought, one of us (R. D. H.) embarked on an investigation of the radiation-induced mutations which could be produced by exposing free-cell cultures of carrot to a cobalt-60 source¹. The basic idea was a simple one. Since carrot tissue can now be grown in free-cell culture² and the free cells spread on agar plates and grown into colonies³, and since the free cells have, under suitable conditions, been grown with the intermediate formation of embryos⁴ into whole plants with flowers, there was every reason to believe that the effects of radiation could be examined using this system. Free cells spread on agar plates should permit one to detect the consequences of a radiation-induced effect in all the cells of the progeny raised from one cell. Thus the exposure of free cells to radiation should be a more effective means of examining the biological effects than by radiating tissues, organs or whole plants (for example, seeds), since any cells so affected by the radiation would transmit the effects only to those cell lines to which they give rise. If the affected cell is isolated and the precursor of a colony, an organ or an organism, the radiation-induced effect should be apparent in the behaviour of the whole.

Prior to this investigation there was some evidence on the effects to be expected⁵. Carrot-tissue explants had

been exposed to cobalt-60 radiation before the onset of growth induction by coconut milk and, by contrast, after the rapid growth rate (for example, 7-8 days of culture) had already taken effect in the coconut milk-supplemented medium. Briefly, the tissue was very sensitive to radiation prior to growth induction—the ultimate site of the coconut-milk growth induction effect being very vulnerable to radiation damage. Similar effects on the same growth response, and presumably at the same sites, which were due to cyanide and to a light-reversible carbon monoxide inhibition, indicate that a cytochrome mediated response was involved. To all these inhibitory treatments (that is, with radiation and cyanide or carbon monoxide) the growing tissue was less sensitive than when it was in the quiescent state. Freshly isolated tissue explants treated with cobalt-60 failed, therefore, to respond to coconut milk by cell division; although at non-lethal doses (up to 0.05 Mrads) the living cells which failed to divide could still expand. Comparable tissue radiated some 7 days later, while it was still in the coconut milk-containing medium, responded quite differently. The already rapidly dividing cells continued to grow and to divide even after exposures to radiation (2 Mrads) which would have completely inactivated the initial site of growth induction by coconut milk. Similarly, the actively growing tissue explants proved to be less sensitive to cyanide, and even the smaller inhibition by carbon monoxide, which could still be observed, differed with respect to its reversibility by light from that obtained with the initial carrot explants⁶.

The first investigations of radiation damage to free cells, exposed on agar plates under such conditions that the cells were so separated that there was no direct contact between them, produced the expected evidence to confirm

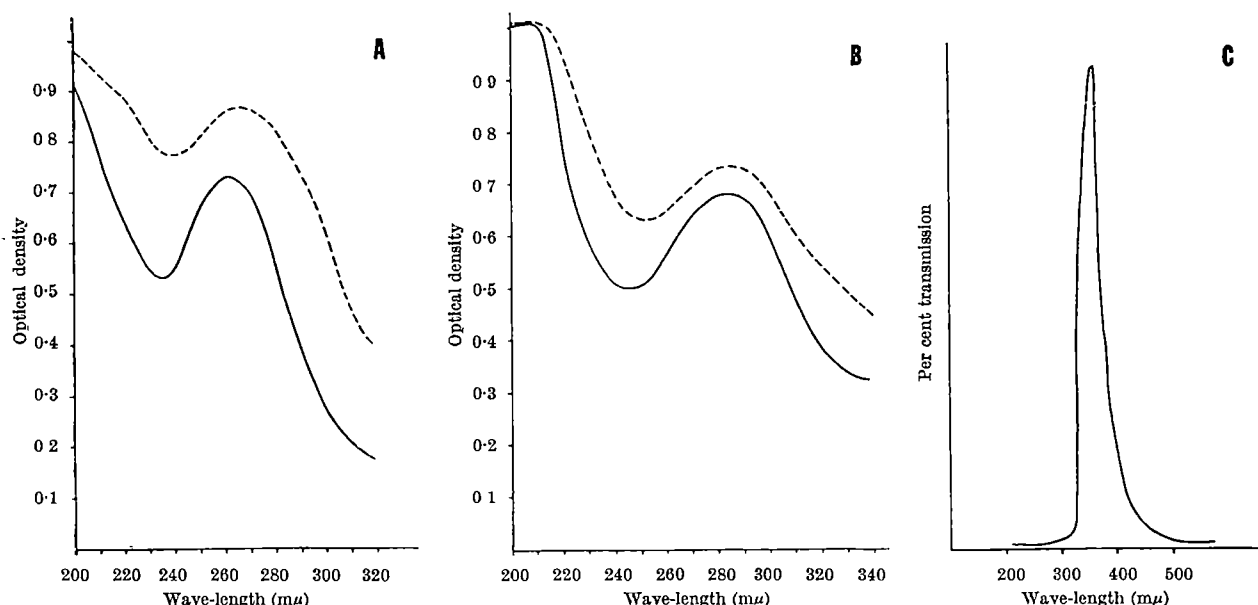

Fig. 1. The ultra-violet absorption and fluorescence spectra of irradiated (2 Mrad) sucrose solutions. *A*, Absorption spectra at pH 4.5, with and without autoclaving, *B*, absorption spectra at pH 11.0, with and without autoclaving, *C*, fluorescence spectrum at an activation wave-length of 290 mμ, at a pH of 4.5. --- Irradiated and autoclaved; —, irradiated

Interpretation: The absorption spectra were determined at pH 4.5 (*A*) and at pH 11.0 (*B*) both with and without autoclaving the irradiated solution. In *C* the fluorescence spectrum of irradiated sucrose is recorded as determined with the Aminco Bowman spectrophotofluorometer at an activation wave-length of 290 mμ at a pH of 4.5

Table 1. EFFECT OF GAMMA-RADIATION ON THE GROWTH OF VIABLE COLONIES FROM FREE CELLS OF CARROT

Radiation dose (Mrad)	Colonies per plate	
	30	35
2.0	0	0
1.0	0	0
0.5	0	0
0.05	10	12
Control	12	16

Interpretation: The cells were irradiated at the dosages indicated, in the basal liquid medium containing coconut milk, and were then diffusely spread on agar plates. The basal medium was that of White¹⁴, slightly modified with respect to calcium and iron, but supplemented with casein hydrolysate as a general source of reduced nitrogen to give greater growth. The plates, sealed against desiccation, were incubated for the periods shown at 70° F in continuous light. The controls passed through all these operations but received no cobalt-60 radiation. Colonies visible to the naked eye were counted and are reported as the mean number/plate in four separate determinations. Colonies still grew virtually unaffected by the radiation at 0.05 Mrad although, at this dosage, the initial tissue would not have grown.

what had been observed previously with the tissue explants (Table 1). However, in making experimental controls, it was observed that the effects in question could be equally as great if one irradiated the culture medium alone prior to placing on it the suspended, viable, non-irradiated free cells or whole explants. It was this observation that prompted the work which will be described in the remainder of this article.

First, it is convenient to state in broad outline the principal outcome of this investigation. As already mentioned, the prior exposure of the culture medium to γ -radiation was found to be as biologically effective as the simultaneous exposure of free cells or tissue explants in the culture medium. Experiments, made to implicate (by methods of elimination) some particular component of the culture medium, clearly pointed to sucrose as the substance by which the indirect effects in question were mediated. At this point, and to obtain better evidence of the nature of the radiolysis products from sugar which inhibit growth as it is induced by coconut milk, samples of ^{14}C -sucrose were radiated and, by autoradiographic means, the range of products so produced was demonstrated. One could also utilize the quite strong ultra-violet absorption (at 260–290 $\text{m}\mu$) of the irradiated sucrose solution to measure its conversion to potentially inhibitory substances.

Only the meagre reports in the literature served as a guide to the kind of substances that might emerge from the γ -radiolysis of sugar and become, thereby, biologically deleterious. Such radiolysis products of sugar, which strongly absorb ultra-violet radiation (260–290 $\text{m}\mu$), comprise several conspicuous compounds which are separable into basic, acidic and neutral fractions on columns of appropriate ion exchange resins. In the outcome, the neutral fraction produced the most outstanding biological effects (it was inhibitory at higher concentration, but somewhat stimulatory when more dilute), and its nature was, therefore, investigated. A simple, three-carbon substance, reductone, reported by Laurent⁶ to be one of the reducing substances produced from glucose by ultra-violet radiation was prepared by one of us (M. S.) according to the directions previously published⁷.

At the time of writing, the balance of evidence is that the synthetic product thus obtained does not nullify the growth induction effect of a coconut milk-supplemented medium, and therefore its identity as reductone, or as a closely related sub-

stance, need not concern us here. Nevertheless, there are, among the products of sucrose radiolysis, other strongly ultra-violet absorbing substances, which are separable on a one-directional chromatogram and are demonstrable by their ultra-violet absorbance, their fluorescence, and by carbon-14 autoradiography. These substances interact strongly with the carrot tissue to produce the equivalent effect of direct radiation on the cells. Furthermore, it was shown that products derived from sucrose by γ -irradiation can also produce chromosomal aberrations in *Vicia faba* and *Tradescantia paludosa* of the kind which would normally be ascribed to the direct effects of radiation. The evidence will be presented here.

Experiments which Demonstrate the Indirect Effects of Radiation on Carrot Cells. In the investigation of the effects of γ -radiation on the growth of carrot phloem tissue in liquid culture, a control experiment was set up in which only the coconut milk growth supplement was exposed to γ -radiation; the results are shown in Tables 2 and 3. Surprisingly, the higher doses of γ -radiation, when applied to the coconut milk supplement alone, produced growth responses in the tissue which were qualitatively similar (though quantitatively somewhat less) to those produced by direct irradiation of the tissue. There were almost no cell divisions observed after the 2- and 4-Mrad treatments and a definite stimulation of cell division followed the treatment at 0.05 and 0.2 Mrad (Table 2).

Fig. 2. Autoradiographic demonstration of the radiolysis products from ^{14}C -sucrose. **Interpretation:** In Fig. A the non-irradiated sucrose (A1) is compared with the irradiated (2 Mrad over 24 h) sucrose (A2). Accentuated breakdown of sucrose to glucose and fructose is evident. In B the same treatments of sucrose were followed by autoclaving and the degradation products are consequently more obvious. In C the dosage of 2 Mrad was delivered over 2 h, with some resultant polymerization, that is, to relatively immobile carbon-14 compounds, and much greater degradation of ^{14}C (C2) compared to its control (C1). C3 shows a strip-scan analysis of the radiolysis products in C2 and several zones of activity are obvious.

Table 2. EFFECT OF IRRADIATED COCONUT MILK ON THE GROWTH OF FRESH-CUT CARROT PHLOEM EXPLANTS IN A BASAL MEDIUM

Initial explants	Radiation dose (Mrad)	Wt./explant (mg)	Cells/explant (in thousands)	Cells/ μ g	μ g/cell
20th day	4.0	3.4	23.10	6.80	0.148
	2.0	5.8	42.36	7.23	0.138
	1.0	15.8	191.53	12.14	0.082
	0.5	41.4	722.26	17.50	0.157
	0.2	61.9	1,080.04	17.38	0.057
	0.05	63.4	1,263.03	19.94	0.050
	none	52.2	959.73	18.34	0.054

Interpretation: The coconut milk, irradiated at the dosages indicated, was incorporated into the basal medium, dispensed into the culture tubes and these were then autoclaved. The fresh-cut explants were removed aseptically from the carrot root and inoculated into the tubes. Growth in weight and number of cells was observed after 20 days under standard conditions. All recorded data are per explant and the average for ten explants. Both the inhibition of cell division at 0.5 Mrad, or greater dosage, and the stimulus observed at 0.2 Mrad, or lesser dosage, were statistically significant; where cell division is active, cell sizes tend to be small; where cell division is less active, cell sizes may increase.

When the carrot phloem explants were caused to grow prior to their exposure to irradiated coconut milk in basal medium (Table 3), they acquired a resistance to the inhibitory effects of the irradiated coconut milk supplement; but there was no sign of stimulated cell division over the controls even at the lowest dosage of γ -radiation used. It is noteworthy that, at the higher dosages of radiation (2 and 4 Mrad), although cell division was noticeably inhibited, cell expansion (expressed as μ g/cell) nevertheless continued (Table 3).

Table 3. EFFECT OF IRRADIATED COCONUT MILK ON THE CONTINUED GROWTH OF CARROT PHLOEM EXPLANTS PRE-GROWN (7 DAYS) ON A BASAL MEDIUM SUPPLEMENTED WITH NON-IRRADIATED COCONUT MILK

Initial explants	Radiation dose (Mrad)	Wt./explant (mg)	Cells/explant (in thousands)	Cells/ μ g	μ g/cell
7th day		3.1	20.75	6.67	0.151
20th day	4.0	11.4	290.16	25.44	0.039
	2.0	131.3	883.19	6.72	0.148
	1.0	159.5	1,185.74	7.41	0.135
	0.5	161.3	1,274.29	7.85	0.129
	0.2	186.5	1,813.33	9.71	0.103
	0.05	199.6	1,961.12	9.80	0.098
	none	183.4	2,096.86	11.43	0.087
		192.1	2,146.74	11.17	0.089

Interpretation: After the prior growth period of 7 days, the cultured explants were transferred aseptically to a medium containing irradiated coconut milk prepared as in the experiment of Table 2. After 20 days the growth was again measured and the data expressed in the same manner as before and as the mean of ten replicates. Even at dosages of 0.5 or more Mrad, substantial cell division continued in these cultures but, since divisions were somewhat suppressed, cells expanded more than in the controls. At the lower radiation dosages (0.2 Mrad, or less) no significant stimulatory effects were observed in this tissue, which had already passed through the growth induction phase.

Having recognized the indirect effects of radiation which could be elicited by irradiation of the coconut milk supplement, the effects of radiating the basal medium were next investigated. The basal medium alone was exposed to γ -radiation and it was then supplemented with non-irradiated coconut milk and inoculated with fresh-cut carrot phloem explants. Again, as with the irradiated coconut milk, growth of the explants was markedly inhibited by irradiating the external basal medium (Table 4). Similar radiation treatments of the medium which received pre-grown (10-day cultured explants in coconut milk medium) explants did not completely suppress their cell division and their continued cell enlargement was

Table 4. EFFECT OF IRRADIATED BASAL MEDIUM ON THE GROWTH OF FRESH-CUT CARROT EXPLANTS AS STIMULATED BY NON-IRRADIATED COCONUT MILK

Initial explants	Radiation dose (Mrad)	Wt./explant (mg)	Cells/explant (in thousands)	Cells/ μ g	μ g/cell
20th day	4.0	3.2	33.68	10.52	0.095
	2.0	3.3	30.62	9.18	0.109
	1.0	2.9	29.78	10.27	0.098
	0.5	3.4	32.57	9.58	0.104
	0.2	33.5	287.12	8.57	0.167
	0.1	85.6	937.64	10.98	0.091
	0.05	97.5	1,291.38	13.37	0.075
	none	115.7	943.57	8.17	0.123

Interpretation: The basal medium, irradiated at the dosages indicated, was supplemented with non-irradiated coconut milk and the subsequent procedures followed those of the experiment of Table 2. At dosages of 0.2 Mrad or more the coconut milk stimulus was unable to exert its normal effect and, at the lowest radiation dosage used (0.05 Mrad), a significant stimulus of cell division was observed.

Table 5. EFFECT OF IRRADIATED BASAL MEDIUM ON THE CONTINUED GROWTH OF CARROT PHLOEM EXPLANTS PRE-GROWN (10 DAYS) ON A NON-IRRADIATED BASAL MEDIUM SUPPLEMENTED WITH COCONUT MILK

Initial explants	Radiation dose (Mrad)	Wt./explant (mg)	Cells/explant (in thousands)	Cells/ μ g	μ g/cell
10th day		4.5	40.36	8.97	0.111
18th day	1.0	25.1	532.95	21.26	0.047
	0.5	45.7	797.08	17.58	0.058
	0.2	60.7	677.57	11.19	0.090
	0.05	86.7	1,187.78	13.78	0.073
	none	88.9	1,172.51	13.25	0.076

Interpretation: The procedure was patterned after the experiment of Table 3 except that the basal medium, not the coconut milk, was irradiated. As will be seen, the effects of radiation which were transmitted to the growing cells were also similar to those described in Table 3.

Table 6. EFFECT OF IRRADIATED SUCROSE ON THE GROWTH OF FRESH-CUT CARROT PHLOEM EXPLANTS IN AN OTHERWISE NON-IRRADIATED BASAL LIQUID CULTURE MEDIUM

Culture medium	Wt./explant (mg)	Cells/explant (in thousands)	Cells/ μ g	μ g/cell
Basal	4.4	20.29	4.5	0.219
Basal + coconut milk + irradiated sucrose	1.4	10.91	8.0	0.128
Basal + coconut milk + non-irradiated sucrose	25.8	452.94	17.8	0.057
Basal + coconut milk	78.5	621.30	7.9	0.127

Interpretation: Randomly sampled batches of fresh-cut carrot explants were inoculated concurrently into (a) the basal medium alone, (b) the un-irradiated basal medium, containing 2 per cent sucrose, plus coconut milk, plus the irradiated sucrose (2 per cent); (c) the same constituents as in b except that non-irradiated sucrose was substituted for the irradiated material; (d) the basal medium, plus coconut milk without any further addition of sucrose. After 18 days the dramatic effect on growth by cell division occurred whenever irradiated sucrose (at 2.0 Mrad) was present in the medium.

consequently less conspicuous (Table 5). In other words, irradiation of the basal medium gave the same type of response as radiating the coconut milk or the complete system including the tissue.

Substance which Mediates the Indirect Effects of Radiation on the Cells. Systematically, and by elimination, the effects of γ -radiation on the various components of the basal medium were tested and it was revealed that the inhibitory effect described was due to an alteration of the sucrose moiety of the culture medium (Table 6). Not only were the various components of the basal medium and of the coconut milk tested separately, but some known products of radiolysis of water (for example, hydrogen peroxide) were also eliminated as causal agents of the effect in question. Since all the culture media used in these investigations were autoclaved, and since autoclaving might be considered to be necessary for the indirect effects of irradiation to become effective, the inhibitory properties of

Fig. 3. Diagram to show chromatographic separation of radiolysis products from sucrose

Table 7. EFFECTS OF AUTOCLAVED AND SEITZ-FILTERED IRRADIATED SUCROSE ON THE GROWTH OF FRESH-CUT CARROT PHLOEM EXPLANTS IN A NON-IRRADIATED BASAL MEDIUM SUPPLEMENTED WITH COCONUT MILK

Medium	Wt./explant \pm S.D.
Basal medium (control)	17.3 \pm 2.2
Basal (sucrose irradiated and autoclaved) + coconut milk	2.6 \pm 0.8
Basal (sucrose irradiated and Seitz-filtered) + coconut milk	4.4 \pm 1.2
Basal + coconut milk (control)	154.1 \pm 17.4

Interpretation: The procedure in this experiment was patterned after the experiment of Table 6. The only difference was that the effects of the irradiated sucrose were determined after 18 days by the weight of the explants. These results confirm those in Table 6 and show that the effect in question was not elicited by autoclaving.

irradiated sucrose, both autoclaved and Seitz-filtered (Table 7), were compared. These results show that the biological effects of irradiated sucrose, though somewhat accentuated by autoclaving, do not require this treatment.

Knowing that irradiated sucrose mediates the biological effects which have been observed in the cultured carrot tissue, the physicochemical properties of the irradiated carbohydrate were investigated. The first change to be noted was the appearance of a prominent reducing power in the irradiated sucrose. This reducing power was markedly increased by autoclaving the irradiated sucrose solution, indicating a further breakdown of the irradiated material under these conditions (15 lb./in.²; 121° C, 15–20 min).

It was also noted that the originally neutral solution of sucrose (pH 7.0) became acid (pH 3.3) when it was irradiated. If the irradiated solution was readjusted to neutrality with base (0.1 N sodium hydroxide) and then autoclaved, the solution again became acid (pH 3.5). The ability of the irradiated sucrose solution to absorb ultra-violet radiation was also noted. As reported for glucose by Laurent⁶ and Phillips *et al.*⁸, and for other carbohydrates by Phillips⁹, irradiated sucrose solutions absorb strongly in the ultra-violet region (Table 8 and Fig. 1).

Using carbon-14 labelled as well as unlabelled sucrose, the products of γ -radiolysis were examined using paper chromatography and autoradiography. At a radiation dose of 2 Mrad, delivered over a 24-h period, there were at least three zones containing unidentified radiolysis products derived from the original sucrose, along with glucose and fructose (Fig. 2). The zone attributed to glucose also contained fluorescent materials (see Fig. 6) and, although the data are not here given, the chromatographic, fluorescence and colour reaction characteristics of at least six products of radiated sucrose have been determined. There was also some generalized streaking of the radioactivity along the length of the chromatogram. The composite diagram of Fig. 3 shows the radiolysis products revealed by autoradiography and by standard colour reactions.

Other Biological Effects of Radiation which are Mediated Indirectly by Radiolysis Products of Sugar. This section will record evidence to suggest that there are other biological effects which may be induced by irradiated sucrose; these comprise effects on meiotic and mitotic cell divisions (observed in *Vicia* roots and *Tradescantia* microspores respectively) and possible mutations in *Drosophila*. The test of the effects of irradiated sucrose on chromosomes was made in buds of *Tradescantia paludosa* which were exposed to a basal medium that contained 2 per cent irradiated sucrose; normal non-irradiated sucrose was used in control

Table 8. ULTRA-VIOLET ABSORPTION OF GAMMA-IRRADIATED SUCROSE SOLUTIONS AS AFFECTED BY pH

	Maximum (m μ)	Minimum (m μ)
Irradiated (pH 4.5)	263	233
Irradiated; autoclaved (pH 4.5), diluted 1:5	268	240
Irradiated (pH 11.0)	285	246
Irradiated; autoclaved (pH 11.0), diluted 1:5	286	252

Interpretation: After irradiation (2 Mrad) the sucrose solution (2 per cent) became acid (pH 4.5) and has a strong ultra-violet absorption with maxima and minima that were affected by pH and greatly so by autoclaving.

cultures employed. The buds were removed daily from these cultures and the dissected anthers stained with Gomori's haematoxylin¹⁰ and their chromosomes examined; Fig. 4 shows the cytological abnormalities which were observed. It is evident from Fig. 4 that irradiated sucrose mediates chromosomal abnormalities which are similar in kind and degree to those attributable to direct radiation of the tissue.

Another experiment was designed to examine the effects of irradiated sucrose on mitoses in roots of young *Vicia faba* seedlings. The results in Table 9 show that the products from irradiated sucrose act as strong antimutagenic agents and they also cause abnormal mitoses and chromosomal aberrations.

Fig. 4. Flower buds of *Tradescantia paludosa* were placed aseptically on a basal medium which contained either 2 per cent irradiated sucrose or, in the controls, the non-irradiated sugar. Buds were removed at three 24-h intervals, the anthers dissected and smears of microspores made and stained with Gomori's haematoxylin as described by Melander and Wingstrand (ref. 10). Obvious chromosomal abnormalities in this meiotic situation are evident in the form of fragmentations (cf. a, b, c); apparent chromosomal bridges (cf. d, e, f and h); unequal divisions and formation of micronuclei (cf. e, f, g and i).

Table 9. EFFECTS OF IRRADIATED SUCROSE ON MITOSIS IN ROOTS OF *Vicia faba* SEEDLINGS

	% prophase	% metaphase	% anaphase	% telophase
2 h	75.3	9.5	9.3	6.3
4 h	69.2	22.0	1.0	7.8
12 h	86.0	7.0	2.0	5.0
24 h	53.0 (17)	17.0 (84)	21.0 (89)	9.0 (18)
48 h	97.6	1.7	0.8 (50)	0
Control	56.5	16.5	17.5	9.5

Interpretation: The roots of young seedlings were immersed in a 2 per cent solution of sucrose which had been irradiated (2 Mrads) and, in controls, in 2 per cent normal sucrose. At the intervals specified, smears were made of root tips, and in the stained preparations the percentage of cells in the various stages of mitosis was determined. The percentages of abnormal nuclei are indicated in brackets in those instances where these were noted. After 48 h treatment with irradiated sucrose only very few divisions still occurred. Through the aid of Prof. C. H. Uhl these results were assembled from many root tips because they were obtained under supervision by a class in cytological technique.

A first test (being subject to confirmation) of the production of sex-linked lethal mutations in *Drosophila melanogaster* when reared on a medium which contained irradiated sucrose was carried out by Miss Carol Sachs in the laboratory of Prof. Bruce Wallace of this University. The results of this experiment are shown in Table 10. When analysed statistically, the effect attributable to irradiated sucrose failed to reach the level of full statistical significance; even so the data are suggestive of an increased mutation rate in the flies reared on the medium containing irradiated sucrose. These results are in substantial agreement with those reported for the effect of ultra-violet radiated glucose on the frequency of mutation in certain bacteria¹¹ and for the frequency of occurrence of sex-linked lethals in cultures of *Drosophila* which had been reared on an irradiated medium¹².

The data presented on *Tradescantia*, on *Vicia*, and on *Drosophila*, concerned with mitotic and meiotic chromosomes of plants and mutation in an insect supplementing the more extensive data on carrot cells in Tables 1-7, together comprise impressive evidence of the indirect biological effects of radiation that may be mediated by sugar—especially sucrose—in the ambient medium and presumably also in the cells. Before describing some further attempts to characterize chemically the biologically active radiolysis products from sugar some other information in the literature may be relevant. The reported incidence of chromosome aberrations in barley embryos¹³ and roots¹⁴ grown on irradiated media could be attributed to breakdown of the carbohydrate in the culture medium in the manner here described. Similarly the anti-mitotic action of extracts prepared from irradiated plants as claimed by Kuzin and Kryukova¹⁵ could be due to breakdown products of carbohydrate. Evidence on these points awaits further enquiry.

Further Attempts to characterize the Biologically Active Radiolysis Products from Sucrose. Relatively large amounts of carbon-12 sucrose were radiated with cobalt-60 at 2 Mrads delivered over a 2-h period. The properties of the radiolysis products (see Table 8 or Fig. 1) could now be used in the attempted isolation of the most active components. The radiated sucrose, after preliminary trials and tests by the carrot assay method, was fractionated as shown in Figs. 5 and 6.

The information contained in Fig. 6 shows the procedures by which the biologically active radiolysis products of sucrose may be isolated, assayed and eventually purified with the view of their final identification; this work is still proceeding. Fig. 7 summarizes the state of the cells, with and without the growth induction due to coconut milk, and emphasizes the effects (direct and indirect) of cobalt-60 radiation on them. Prior to the large synthesis of nucleic acid (and formation of ribosomes), which pre-

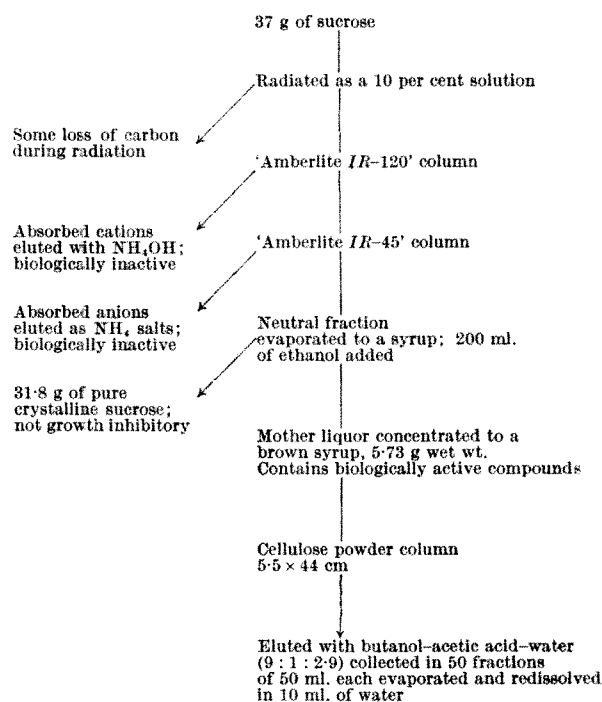

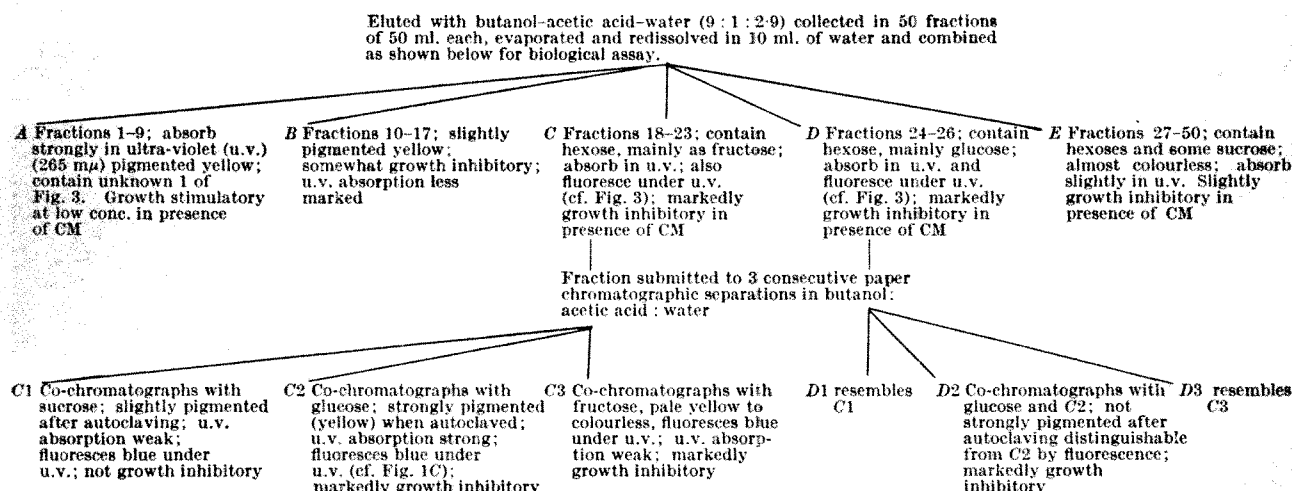

Fig. 5. Separation of radiolysis products from sucrose

In summary, cobalt-60 radiolysis produces in small amount many new substances; individually they account for only a small part of the weight of the sugar. Several of these compounds are strongly unsaturated, fluoresce, and become more pigmented on autoclaving (Fig. 1). Among these substances are those which are responsible for the growth-inhibitory properties at higher concentrations and the growth-stimulatory properties at lower concentrations; these effects are exerted at the site at which the growth induction due to coconut milk normally acts. They also have other biological effects to which reference has been made.

Fig. 6. Properties of radiolysis products from sucrose: sub-fractions of the neutral fraction eluted from the cellulose powder column

Table 10. EFFECT OF IRRADIATED SUCROSE ON MUTATIONS IN *Drosophila melanogaster*

	Frequency of sex-linked lethals	% lethals
Irradiated sucrose	5/1000	0.5
Control sucrose	1/500	0.2

Interpretation: This system was set up for the purpose in the laboratory of Prof. Bruce Wallace. *SC* wild-type flies were grown on a normal culture medium with and without 2 per cent irradiated sucrose (2 Mrad). The male progeny from these populations were mated to Muller-5 females. Mutations caused by the irradiated sucrose on the X-chromosome of the *SC* males will be carried in the female progeny of this mating. By brother-sister matings in this programme, the occurrence of sex-linked lethals may be revealed by the abnormal proportions of red-eyed male progeny. Thus the test of the incidence of mutation is the frequency of red-eyed males in the population, for a sex-linked lethal, due to the sucrose, would render the red-eyed males inviable. From these results the incidences of mutation could be calculated, and these are shown as percentages.

cedes the cell division caused by the coconut milk (that is, 0-4 days), the cells are very sensitive to cobalt-60 radiation (Tables 2 and 4); subsequent to this time and after cells are in the dividing state they are much more resistant (Tables 3 and 5). There is a suggestive parallel here with certain work on bacteria¹⁷.

Concluding Remarks. The work here described has a potential impact on currently important biological problems as follows:

(1) A strong antimetabolite from irradiated sugar, which can overcome the growth induction due to coconut milk, or even stimulate it further at low concentration, contributes to an understanding of the site of action of the growth stimulus and to the interpretation of a balanced set of chemical controls which either release or suppress the ability of the cells to grow.

(2) If the deleterious effects of radiation on cells may be mediated indirectly through its effects on sugar, present either in the cells or in the medium, this is important for the understanding of the mechanism of radiation-induced effects. These ideas lead to obvious biologically important questions that may now be investigated. In particular, the stability of the radiolysis products raises questions concerning their longevity in

cells, or organisms, for this has an important bearing on the relative importance of the direct and the indirect effects of radiation.

(3) The work has other and obvious implications for the radiation sterilization of food, especially in those cases in which the material so radiated is relatively rich in sugar. If radiation effects may be transmitted to cells via stable radiolysis products derived from sugar, one should clearly know whether or not these have biologically important consequences, both short and long term, before there is widespread use of radiation-sterilized foods that contain sugar.

(4) Much more needs to be known, than is available in the literature, or in this paper, of the chemical consequences of submitting sugar to radiation, particularly γ -radiation from cobalt-60. Sufficient has, however, been said to show that the biologically active substances produced from sugars by radiation can now be recognized and isolated and, in the carrot-coconut milk tissue culture system, there is a precise means available for the assay of their effects on growth by both cell division and cell enlargement. Further work of this kind is now in progress.

In short, the experiments which started as an investigation of radiation-induced mutations in isolated cells (still a worthy objective to which we shall return) have raised biologically important questions to which final answers should be found. The purpose of this article is to make these findings widely known, for, although the evidence is largely drawn from higher plants, it nevertheless has obvious potential bearing on other living systems, for it stresses that the effects of the radiation are neither confined to their direct effects on the cells nor to the immediate period of exposure to the radiation.

During part of this work Dr. Holsten worked under pre-doctoral fellowships of the National Science Foundation and the National Institutes of Health as directed by one of us (F. C. S.) and most of the results presented here were embodied in his thesis for a Ph.D. degree.

Fig. 7. Characteristics of the tissue culture system, with respect to growth and nucleic acid content, which responds to cobalt-60. A depicts the changes with time in the nucleic acid content of carrot cells in explants which undergo the growth induced by coconut milk (+ CM); B describes the changes in the number of cells in carrot explants which grow by cell division in the presence of coconut milk (+ CM) or merely enlarge in its absence (- CM); C depicts the changes in the nucleic acid content of carrot cells in explants which lack the growth stimulus of coconut milk (- CM). In B the arrow at (1) indicates the time of application of cobalt-60 radiation which thereby inactivated the cell division response otherwise due to CM, though it still permitted growth by cell enlargement. The arrow at (2) indicates the time of application of cobalt-60 radiation to growing cells, which were much more resistant to the radiation than those which had not undergone prior growth induction. A and C respectively show the nucleic acid content at these times.

Dr. M. Sugii, of the Institute for Chemical Research, Kyoto University, Takatsuki, Osaka, Japan, was able to work on this problem at Cornell University under arrangements made possible by a grant (GM09609) to one of us (F. C. S.) from the National Institutes of Health, U.S. Department of Health Education and Welfare; Dr. Sugii's contribution related to the more chemical fractionation of the radiated sucrose.

All other laboratory work was made possible by the research grant cited. This included the help with the aseptic procedures provided by Mrs. M. O. Mapes and by certain research assistants to one of us (F. C. S.).

For the radiation treatments we thank the Geneva Experiment Station of Cornell University and also the Nuclear Reactor Laboratory at Ithaca, New York, for access to their cobalt-60 sources.

NATURE OF THE HEPATOMEGALIC EFFECT PRODUCED BY ETHYL-CHLOROPHENOXY-ISOBUTYRATE IN THE RAT

By Dr. R. HESS, W. STÄUBLI and W. RIESS

Research Laboratories, Pharmaceutical Department, Ciba, Ltd., and Laboratory of Electron Microscopy, University of Basle, Switzerland

ETHYL- α -(*p*-chlorophenoxy)isobutyrate (CPIB), a compound with hypolipidaemic properties in man¹ as well as in animal species², has been found^{3,4} to cause enlargement of the liver in male rats when added to the diet at a level of 0.25 or 0.3 per cent. This hepatomegalic effect occurred without accumulation of lipids in the liver tissue and it was supposed to be a non-specific change caused by metabolic conversion of CPIB (ref. 3). In livers of rats treated with CPIB for no longer than one week, an increase in the size of the hepatocytes was noted by Paget⁵ and this change appeared to be related to an accumulation of lysosome-like organelles within the cytoplasm.

In order to elucidate further the structural basis of the hepatomegalic effect, male albino rats on a standardized diet were given daily oral doses of 500 mg/kg CPIB for 14 days. This dosage caused a mean 41 per cent decrease in serum cholesterol concentration and also inhibited the animals' weight gain. As shown in Fig. 1, the relative liver weight rose rapidly during the first week of treatment and fell again to pre-treatment levels after CPIB was withdrawn. At the time-intervals indicated in Fig. 1, liver tissue was fixed in buffered 2 per cent osmium tetroxide using either the technique of Palade⁶ or that of Millonig⁷. Following embedding of the tissue in 'Araldite' or 'Epon 812' ultra-thin sections were prepared on a Porter-Blum (MT 1) microtome, stained with either lead hydroxide⁸ or with lead citrate⁹, and examined in a Siemens Elmiskop I operated at 80 kV.

Treatment with CPIB for 14 days gave rise to a marked increase in liver-cell organelles showing the morphological characteristics of microbodies^{10,11} (Figs. 2 and 3). In normal rat liver many of the microbodies contain an array of tubular elements that form a 'nucleoid' or core^{11,12}. In liver cells from treated rats, the microbody-like structures were mostly without cores, indicating that CPIB had caused the formation of an incomplete and aberrant type of organelle. Although the diameter of the 'microbodies' following CPIB treatment was found to vary within wider limits than in normal liver (mean diameter 0.5–0.6 μ), the single membrane and the appearance of the finely granular matrix were not visually altered.

The increased formation of 'microbodies' appeared to be a very rapid process since these organelles were much more numerous 24 h after the first dose of CPIB. The accumulating 'microbodies', some of them in clusters, were distributed throughout the cytoplasm. There was no obvious association with other cytoplasmic constituents except that, in part, the 'microbody' membranes were connected to the smooth-surfaced endoplasmic reticulum by means of short, hook-like or finger-like extensions¹³. CPIB treatment caused no increase in 'multivesicular bodies', that is, particulate structures which have been considered to develop into microbodies¹⁴. By contrast, elements of the smooth-surfaced endoplasmic reticulum proliferated in response to the first dose of CPIB.

Despite the fact that the liver weight returned to normal values following the withdrawal of CPIB (Fig. 1), there was still an increased number of microbodies present 14 days after the cessation of treatment. The microbodies appeared to be broken down in part by the mechanism proposed by Novikoff and Shin¹⁵ which leads to the formation of 'autophagic vacuoles'. In contrast to the slow removal of microbodies, the CPIB-induced pro-

Fig. 1. Liver hypertrophy produced by oral administration of CPIB. Each point represents the mean of values for 2 male rats

Figs. 2 and 3. Electron micrographs of comparable cytoplasmic areas of normal liver cell (Fig. 2) and of liver following treatment with 500 mg/kg/day of CPIB for 10 days (Fig. 3). Microbody-like structures (arrows) are increased in number.

liferation of smooth-surfaced endoplasmic reticulum regressed rapidly after treatment was discontinued.

Biochemical changes occurring during treatment were examined in liver tissue from male rats following daily oral treatment with 300 mg/kg CPIB for 7 days. A mean 29.3 per cent increase in relative liver weight ($P < 0.01$) was obtained and this effect was unaccompanied by significant alterations in liver content of total lipid, phospholipid, and total cholesterol relative to the wet weight of tissue. A decrease in relative cholesterol content (mean 33 per cent) was attained in a separate experiment after 4 weeks of treatment with the same dose. In principle, these findings agree with earlier reports^{3,4}.

Since the protein content per g of liver was the same in treated animals as in the controls (Table 1), it could be assumed that the increase in the number of microbodies had in part contributed to the actual rise in total liver protein. These organelles have been shown to contain the bulk of hepatic catalase, urate oxidase and D-amino-acid oxidase activity¹⁵. In order to follow up, by

means of enzymatic parameters, changes in the population of cellular organelles we observed in the electron microscope, catalase¹⁶, urate oxidase¹⁷, and cytochrome oxidase¹⁸ were assayed in 1:10 (w/v) liver homogenates prepared at 0° in 0.25 M sucrose containing tris(hydroxymethyl)aminomethane 0.05 M pH 7.4 and 6 per cent 'Ficoll' (mol. wt. 400,000; Pharmacia, Uppsala). Mitochondrial glycerol-1-phosphate dehydrogenase (GPD) activity was determined in homogenates from the same livers¹⁹. The results (Table 1) demonstrate an increase in specific activity of the mitochondrial enzymes cytochrome oxidase and GPD, which was accompanied by a decrease in urate oxidase activity and a small but significant increase in catalase specific activity. Owing to the increase in liver weight, the decrease in urate oxidase activity possibly reflects dilution. This appeared to be related to the accumulation of microbodies deficient in crystalloid cores which were seen in the electron micrographs of livers following treatment with CPIB. The cores have been tentatively identified as bearers of urate oxidase^{12,15}.

An attempt was made to separate microbody-like particles from mitochondria (obtained at 480,000g min) by density equilibration centrifugation in 'Ficoll' density gradients (mixed from two stock concentrations, each containing 'Ficoll' in a mixture of isotonic sucrose:tris buffer pH 7.4 = 2:1). Particles from normal liver were fractionated at densities ranging from 1.1728 g/ml. to 1.1890 g/ml. This resulted in the resolution of catalase and urate oxidase activity in two peaks. By contrast, a gradient of lower density (1.1643–1.1748) had to be used to separate liver particles following CPIB treatment. A considerable overlap of all the cytoplasmic particles was observed in these preparations and no clear separation was achieved. This different behaviour of particles from normal and CPIB-treated livers might depend on some structural alteration caused by the treatment. That this may be the case was also suggested by a tendency for catalase to be released into the post-mitochondrial supernatant of preparations from treated liver. Catalase activity has been associated with the structureless 'sap' of microbody-like particles^{12,15}. After centrifugation of the particulate fractions in the tris-sucrose-'Ficoll' medium at 1.28×10^6 g min the supernatant fraction contained 36 per cent of the total catalase activity of normal liver, but 69 per cent of recoverable activity in the case of liver from CPIB-treated animals.

It is not readily apparent whether, in the rat, the hepatic enlargement associated with accumulation of microbody-like organelles has any relationship to the hypolipidaemic effect of CPIB. The physiological role of these particles remains virtually unknown¹⁵.

The inhibitory effect of CPIB on cholesterol synthesis *in vivo*⁴ might rather be explained by the changes we have observed to occur in the endoplasmic reticulum. Stimulation of microsomal systems is a property of a number of cholesterol synthesis inhibitors²¹. According to Thorp²², CPIB may act by raising the relative concentration of thyroxine in the liver. The increase in mitochondrial activity, particularly of GPD, observed in the present experiments, seems to fit in with this assumption. It has been shown^{19,23} that, at the tissue-level, both endogenous and exogenous thyroid hormone is capable of selectively stimulating mitochondrial GPD activity. Both

Table 1. EFFECT OF CPIB ON LIVER ENZYME ACTIVITIES OF RATS

Animals	Protein mg/g wet wt.	Catalase	Urate oxidase	GPD	Cytochrome oxidase
Controls	119.0 ± 8.6 (10)	8.20 ± 1.55 (6)	95.12 ± 49.7 (8)	0.313 ± 0.13 (5)	0.86 ± 0.058 (3)
CPIB	127.8 ± 14.4 (20)	10.46 ± 2.78 (15) $P < 0.05$	40.39 ± 32.2 (19) $P < 0.02$	1.95 ± 0.42 (7) $P < 0.001$	1.50 ± 0.540 (6) $P < 0.05$

Enzymatic activity per mg of protein of total homogenate is expressed as follows: catalase, μ moles of H_2O_2 decomp./sec.; urate oxidase, μ moles of uric acid ox./h; GPD, μ moles of formazan prod./h; cytochrome oxidase, μ moles of reduced cytochrome c ox./min. Protein was measured according to Lowry *et al.* (ref. 20). Mean values ± S.D. and no. of animals (in brackets) are given; significance of difference (P) is ascertained by t -test. CPIB was administered daily by gavage at a dose of 300 mg/kg for 7 days.

the latter effect and the hepatomegaly (including the accumulation of microbodies) produced by CPIB may be attributed to altered co-factor availability since, in preliminary experiments, the hepatic effects of this drug could be inhibited by simultaneous treatment with the ATP-trapping agent ethionine²⁴ (14×250 mg/kg/day) but were not affected by puromycin (3×3 mg/kg/day) or actinomycin D (1 mg/kg/day). (The latter substance was kindly supplied by Merck, Sharp and Dohme, International.)

A LOCALIZED HAEMOLYSIS IN GEL METHOD FOR THE DETECTION OF CELLS PRODUCING 7S ANTIBODY

Detection of Cells producing 7S Antibodies by the Plaque Technique

THE kinetics of the appearance of antibody-forming cells after the injection of sheep red blood cell (sheep-RBC) antigen have been studied by the plaque technique^{1,2}. The number of plaque-forming cells before immunization is about 60 per 10^8 lymphoid cells; but after immunization the number rises to a maximum between the 4th and 5th day of about 30,000 in 10^8 lymphoid cells. After the 5th day there is a rapid decline in the number of plaques so that on the 13th day there are only 2,000 per 10^8 lymphoid cells. The kinetics of serum haemolytic antibody appearance are consistent with its production by plaque-forming cells. In contrast to this, serum haemagglutinating antibody does not reach a maximum until the 10th day post-immunization and afterwards persists considerably longer than haemolytic antibody. The differences between haemagglutinins and haemolysins could be related either to antibodies directed against different antigenic specificities on the erythrocyte or to the heterogeneity of antibodies directed against identical specificities, or both.

It has been found that the antigenic determinants evoking haemolysins can be dissociated from those evoking haemagglutinins³. When sheep-RBC were treated with 0.5 per cent or 1 per cent formalin for a few days they lost the capacity to induce haemolysin formation but retained unchanged their capacity to induce haemagglutinins. It follows that the haemolysins and haemagglutinins were directed against different antigenic groups.

In further experiments we have examined the plaque-forming ability of 19S and 7S producing cells. 19S antibodies are known to be much more effective in inducing haemolysis than the 7S antibody⁴. However, Riha found that he could increase the haemolytic activity of 7S antibodies by the addition of an antiserum specific for the 7S antibodies⁵.

In the experiments described here we used this principle in combination with the plaque technique to detect the production of 7S antibodies by individual cells. We have used the plaque technique previously described^{6,7}. Cells isolated from the spleen or lymph nodes were washed three times and suspended to the required concentration in Parker 199 solution with 0.5 per cent human serum albumin (HSA) and brought to 42° C. One part of the lymphoid cell suspension was added to two parts of agarose solution containing washed sheep-RBC (3 parts 1 per cent agarose with 1 part 6 per cent sheep-RBC; in Parker 199/HSA) which was also at 42° C. The mixture of cells,

sheep-RBC and agarose was pipetted dropwise from a height of about 60 cm into a Petri dish or on to a slide. This resulted in the drop forming a flattened spot with a diameter of 18 mm. The spots were allowed to harden and were then incubated at 37° C in a humid atmosphere with 5 per cent carbon dioxide for 6–20 h. After the incubation the individual 'spots' were overlaid with the anti- γ G serum. This antiserum was prepared by immunization of a different species with the γ G from the species the plaque-forming cells of which were to be examined. The antiserum was allowed to remain on the agarose spots for 1 h at 4° C and was then washed off with veronal buffer⁸. Finally, guinea-pig complement (20 units/ml.) previously absorbed with sheep-RBC was added. The anti- γ G serum was equally effective when incorporated into the agarose solution at the start of the procedure, and for routine work this procedure is recommended.

The number of plaques formed varied greatly with the concentration of anti- γ G serum (Table 1). There was an optimal concentration for maximal development of plaques; higher concentration resulted in inhibition. Plaque formation by 19S-producing cells was also inhibited at high concentrations, presumably because of the presence of antibodies directed to the L chain, which are common to 7S and 19S molecules.

In order to study the morphology of individual cells forming 7S and 19S antibodies, the following method was used. The medium with cells and sheep-RBC was incubated without anti- γ G and developed with complement. The plaques thus formed (mainly 19S) were then marked and the complement washed off; the anti- γ G was then added and followed by a second incubation with complement.

The kinetics of the appearance of antibody cells detected with and without added anti- γ G are shown in Fig. 1. On the 5th day after immunization with sheep-RBC the number of cells detected after the addition of anti- γ G

Table 1. INFLUENCE OF ANTI- γ G SERUM ON THE NUMBER OF ANTIBODY-FORMING CELLS

	Complement only	Anti- γ G serum + complement 1:5	1:50	1:100
Rabbits (secondary * reaction)	23,000	7	121,000	— (a)
	6,000	660	75,000	— (a)
	5,500	—	40,000	39,000 (b)

‡ Rabbit antiserum to mouse γ G.

was not greater than the number seen on the addition of complement alone. On the 10th day only 27 per cent of the total plaque-forming cells are detected by complement alone. By the 14th day 92 per cent of the plaques are detected only if the anti- γ G is added. The serum haemolysin titres of these mice are also shown in Fig. 1. The peak of haemolytic antibody detected by complement alone is reached within 5 days and falls after the 10th day. The peak of haemolytic antibody detected by complement plus anti- γ G is not reached until the 10th day.

It was demonstrated that the quality of haemolytic antibody in these mice also changes (Fig. 2).

The partition of serum by either 'Sephadex-G 200' or density gradient ultracentrifugation revealed that 5 days after immunization only high molecular weight antibodies were present. They were sensitive to treatment with

2-mercaptoethanol. By the same technique it was shown that serum from mice 14 days after immunization contained predominantly 7S antibody, which was resistant to treatment with 2-mercaptoethanol. However, it must be borne in mind that changes in serum antibody may appear later than changes observed at the cellular level.

We conclude that the addition of anti- γ G increases the detection by the gel-technique of 7S antibody-producing cells. This enables us to follow quantitative changes in cells producing 19S or 7S antibody.

Use of an Antiglobulin Serum to detect Cells producing Antibody with Low Haemolytic Efficiency

THE microdroplet and immunofluorescent techniques have been used extensively for the study of antibody production by single cells¹. Recently, a third method has been established which uses a semi-solid supporting medium in which antibody-producing cells have been incorporated². The basis of this localized haemolysis in gel (LHG) technique is to set up a mixed suspension of sheep-RBC and dissociated lymphoid cells from an animal previously immunized against sheep-RBC. Antibody (haemolysin) diffuses from some of the lymphoid cells and binds to the sheep-RBC in the medium; complement is added and small areas of haemolysis (plaques) develop around these lymphoid cells.

It appears, although it has not formally been proved, that the LHG technique is limited to the detection of γ M antibody³. This conclusion is based on the observation of a parallel rise and fall of both serum haemolytic activity, mainly due to macroglobulin antibody, and plaque-forming ability. It is also consistent with the knowledge that 19S antibody is far more efficient than 7S in effecting complement-dependent lysis of sheep-RBC⁴.

This article reports the details of a method devised to adapt the LHG method for the detection of cells forming antibody with low haemolytic efficiency. Mouse antibody to sheep-RBC, produced by lymphoid cells suspended in agarose, is allowed to react with the sheep-RBC in the medium; a rabbit anti-mouse immunoglobulin serum is then allowed to react with the complex; finally, complement is added and in zones around certain lymphoid cells the sheep-RBCs lyse, forming plaques visible to the naked eye. This is illustrated diagrammatically in Fig. 1.

An antiserum against mouse immunoglobulin was raised in Himalayan rabbits, which were immunized with a preparation of a normal mouse γ G in Freund's adjuvant, followed by intravenous boosters of the mouse γ G in saline. The γ G was prepared from ascites fluid of CBA mice carrying a C3H plasma cell tumour (No. 5563) as an ascites. It was separated from γ G myeloma and other serum proteins on a DEAE-cellulose column⁵. Control sera (NRS) were obtained from Himalayan rabbits. Fresh guinea-pig serum was used as a source of complement. All sera used were absorbed with sheep-RBC and in addition the rabbit sera were heated at 56° C for 40

min to destroy complement. The donors (CBA mice) of the lymphoid cells, in this case spleen cells, were immunized by a single intraperitoneal injection of 0.5 ml. of a 20 per cent suspension of sheep-RBC (2×10^9 cells) in Gey's solution. The technique was as follows:

(1) Disposable polystyrene Petri dishes, 9 cm in diameter, were used in these experiments.

(2) 10 ml. of 1.2 per cent (w/v) agarose (L'Industrie Biologique Française) in Dulbecco's phosphate buffered saline were added to each Petri dish and allowed to set on a level surface; these plates could be stored for up to 24 h at 2° C. All agarose solutions were made by melting the powder in 1/5 the final volume and then adding the rest of the buffer, suitably warmed. This was done because the smaller volume is more easily managed, thus helping to prevent loss of material due to boiling over. The prepared plates were warmed to 37° C immediately before addition of the medium containing the cells.

(3) Lymphoid (spleen) cells were suspended in Gey's solution with a very loose-fitting glass homogenizer. Cell suspensions were poured through a 150 μ hole stainless-steel wire mesh and the volume adjusted to give 10×10^6 viable cells per ml. Cell counts were made by phase contrast microscopy and estimates of viability were made by counting the number of cells which excluded eosin. More than 100×10^6 cells per spleen were always obtained and of these more than 75 per cent were scored as viable.

(4) Sheep-RBC in Alsever's solution (Burroughs Wellcome and Co.) were washed three times with Gey's solution (5-min centrifugation at relative centrifugal force of 800*g*) and then made up to a 20 per cent suspension in Gey's solution.

(5) For each plate, 2 ml. of 0.6 per cent agarose in Gey's solution were pipetted into a 1.3 \times 10 cm test-tube held in a rack in a water bath at 47° C.

(6) A tube was removed from the bath, the outside dried and 0.1 ml. of the 20 per cent sheep-RBC suspension rapidly pipetted into it. The contents were mixed and 0.1 ml. (1×10^6 cells) of the lymphoid cell suspension added. The contents were mixed again and poured into the prepared Petri dish. This top layer was spread by a swirling motion and allowed to set on a level surface.

(7) Plates were incubated for 1 h at 37° C in a moist atmosphere of 5 per cent carbon dioxide and 95 per cent air.

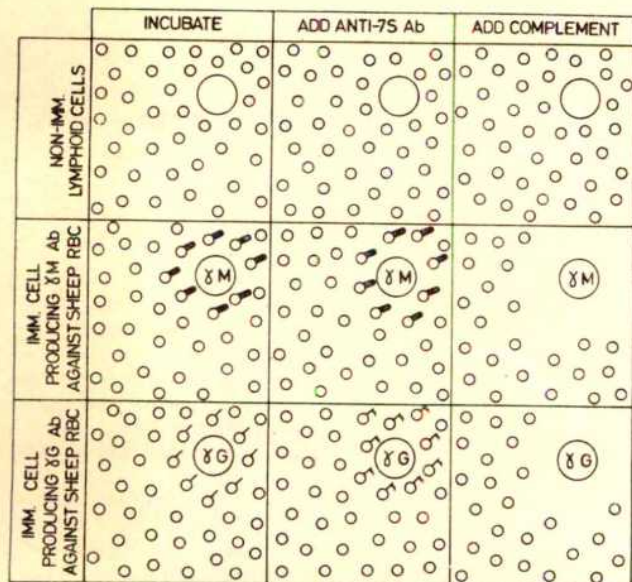

Fig. 1. A diagram to illustrate the theoretical basis of the technique. The large circles represent mouse lymphoid (spleen) cells producing no antibody, γ M type antibody or γ G type antibody. The small circles represent sheep-RBC which was the antigen and indicator cell used in these experiments. The broad and narrow bars represent γ M and γ G antibody molecules respectively, both directed against sheep-RBC. The bent bars (bottom centre) represent rabbit antibody molecules specific for mouse γ G globulins.

Fig. 2. This figure shows the difference between a control plate (16 plaques) and a plate treated with 1/10 rabbit anti-mouse immunoglobulin serum (548 plaques). The mouse spleen cells used in both these plates were obtained 14 days after immunization with sheep-RBC.

(8) 2 ml. of a stated dilution of the rabbit anti-mouse immunoglobulin serum were carefully pipetted on to the surface of the plate and gently spread. 2 ml. of normal rabbit serum at the same dilution were used in control experiments. Further control experiments were carried out without the addition of either antiserum or normal serum (see top line of Table 1). The plates were incubated for 1 h at 37° C.

(9) The added rabbit serum was then poured off. 1 ml. of a 10 per cent solution of fresh guinea-pig serum in Gey's solution was added to each plate as a source of complement. The plates were incubated for 30 min at 37° C.

(10) The complement was poured off, the plates inverted and the plaques counted with dark-field illumination with the aid of a slight magnification. This could be done immediately or after the plates had been stored for up to 24 h at 2° C.

Table 1 shows the effect on the development of the plaques of adding either rabbit anti-mouse immunoglobulin or normal rabbit serum. In each case the number of plaques seen are expressed as a factor of the number of plaques which developed in untreated control plates (see top line of Table 1). At 2 and 4 days after immuniza-

Table 1

The table summarizes the results of experiments designed to show the effect of normal rabbit serum (NRS) and rabbit anti-mouse γ G on the number of plaques developing *in vitro* at different times post-immunization of the spleen cell donors

	1/2,430	0.83	0.99	1.06	1.39	2.50	

* No. of plaques per 10^6 spleen cells on untreated (control) plates. Figures in parentheses are the No. of mice used. Duplicate plates were made from the cells of each mouse.

† Each result is based on two plates from each of two donor mice (4 plates/result) and the figure given is a factor = $\frac{\text{No. of plaques with added serum}}{\text{No. of plaques on untreated plates}}$.

A factor of 0.08 shows a very marked inhibition of plaques; a factor of 13.02 shows a great increase of plaques, compared with controls.

tion of the lymphoid cell donors the addition of either NRS or antiserum depressed the number of plaques formed. At 7 days, NRS neither suppressed nor increased plaque development, but the plates treated with the antiserum at a 1/30 dilution showed a greater than three-fold increase in number of plaques. Eleven days after immunization there was only a slight increase in the number of plaques seen with NRS treatment but a very large increase with the addition of the antiserum; the optimum antiserum dilution was about 1/90. At 37 days post-immunization there was still a distinct difference between NRS and the antiserum, the latter giving at least ten times more plaques than the NRS with both sera at a dilution of 1/30. The effect of adding antiserum is shown in Fig. 2.

We believe that the plaques which appeared when the plates were treated with antiserum were due to antibody with low haemolytic activity, such as γ G antibody. We base this argument on the following observations: (a) the maximum number of these plaques occurred when γ M(19S) antibody was past its peak level; (b) antiserum

had opposite effects on the development of plaques formed soon after immunization and those formed later, which suggests that different types of antibody and/or cells were being affected; (c) the antiserum was primarily anti- γ G and was probably acting by virtue of its specific anti- γ G activity. The antiserum used reacted strongly with the F piece (piece III) of a papain digest of a γ G myeloma (plasma cell tumour No. 5563), but had only a minimal reaction with the S piece (pieces I and II) which contains the antigenic determinants common to all the immunoglobulins⁶. It is unlikely that the antiserum developed plaques solely because of its low reactivity with common determinants. If the serum action did depend on antibody activity against common determinants it would be difficult to understand how the same serum could decrease the number of visible plaques at 2 and 4 days post-immunization and yet increase the number of visible plaques at later times. It therefore seems unlikely that the antiserum acts by damaging γ M-containing cells that would otherwise not release their antibody. However, until more specific antisera are used it will be impossible to know the relative contributions of the cells producing different classes of immunoglobulins.

We thank Drs. R. B. Taylor and D. R. Bainbridge for suggestions, and Miss Doreen Cross for assistance. One of us (H. H. W.) was supported by an Arthritis Foundation (U.S.A.) post-doctoral fellowship.

A NEW MODEL FOR VIRUS RIBONUCLEIC ACID REPLICATION

By DR. F. BROWN and DR. S. J. MARTIN

Animal Virus Research Institute, Pirbright, Woking, Surrey

SUBSTANTIAL evidence now exists to support the initial observations of Montagnier and Sanders¹ that the multiplication of virus RNA proceeds via a replicating form. This form is readily differentiated from the RNA which is present in the complete virus particles by its considerably slower rate of sedimentation in sucrose, lower buoyant density in caesium sulphate and resistance to degradation by ribonuclease. It has been postulated that this replicating form permits the preferential synthesis of new virus RNA (corresponding to the plus strand) on a primer (minus strand) which is initially coded for by the ingoing virus RNA. This replicating form is envisaged as containing a double-stranded region as well as a number of single-stranded tails, corresponding to partially formed plus strands (Fig. 1a)²⁻⁴. Such a molecule would possess a lower buoyant density than single-stranded RNA and it has been assumed that ribonuclease will remove the single-stranded tails, leaving only a double-stranded molecule (Fig. 1b).

Certain features of this model, however, do not account for all the experimental evidence available. In the first place, it has been shown that the ribonuclease-resistant RNAs present in cells infected with EMC⁵, foot-and-mouth disease⁶ and poliomyelitis⁶ viruses possess low but signi-

ficant infectivity. Unless the minus strand is infective, which is extremely unlikely, the infectivity must be contained in the plus strand. In the model which is at

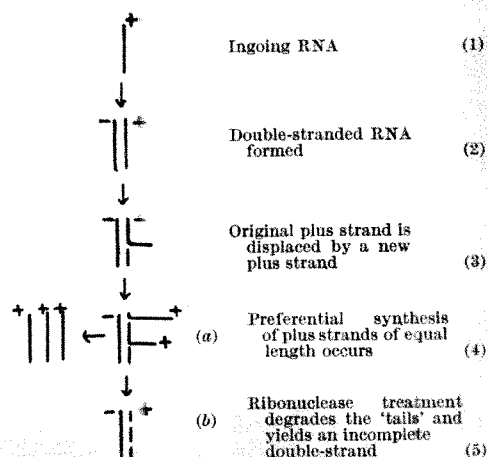

Fig. 1. Diagrammatic representation of the replicating mechanism of virus RNA which is at present accepted

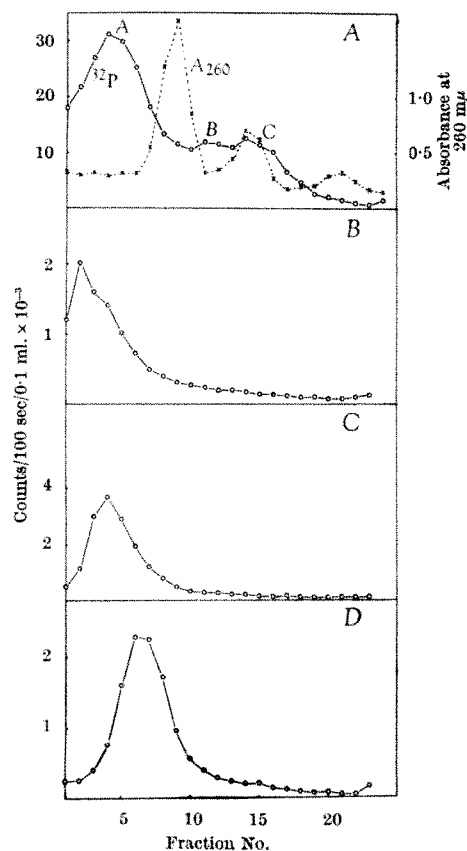

Fig. 2. Sedimentation in sucrose gradients (5–25 per cent sucrose in 0.1 M acetate, pH 5.0) of 'Sephadex G-200' filtered RNA from actinomycin D treated BHK cells, 4 h after infection with FMD virus. (A), Total RNA; (B), fraction 2 from first sedimentation recycled in a second gradient; (C), recycled fraction 4; (D), recycled fraction 6. The RNA was centrifuged for 16 h at 20,000 r.p.m. in an SW 25 rotor in a Spinco ultracentrifuge at 4°. Unlabelled BHK cell RNA was added to each sample before centrifuging to serve as an internal marker.

present favoured, the plus strand of the ribonuclease-resistant RNA would not be an intact virus RNA strand but a collection of RNA molecules, each shorter in length than the virus RNA. All the evidence so far accumulated in a number of laboratories has shown that the intact virus RNA molecule is required for infectivity^{7,8}. Secondly, the ribonuclease-resistant RNA in the model shown in Fig. 1b is a double-stranded molecule which has gaps between adjoining segments of the residual plus strands. It is questionable whether such a molecule would be stable to relatively high concentrations of ribonuclease, for example, 50 $\mu\text{g}/\text{ml}$.⁹

A model for the replicating form which accounts for these experimental findings should contain a complete double strand as the ribonuclease-resistant part of the structure. Additional experimental evidence which we have derived from an examination of the RNA molecules synthesized in baby hamster kidney cells infected with foot-and-mouth disease virus supports this supposition and has led us to propose a new hypothesis for virus RNA replication. Our hypothesis is based on a cyclic mechanism similar to that which is thought to be involved in the replication of DNA phages.

In a previous report from this laboratory, Brown and Cartwright⁶ demonstrated that three peaks of ³²P-labelled RNA were formed in the presence of actinomycin D during foot-and-mouth disease virus replication in baby hamster kidney cells. These fractions were separated by sucrose-gradient sedimentation and have approximate sedimentation coefficients of 37S, 20S and 16S (peaks A, B and C, Fig. 2A).

This work has now been extended to a more detailed investigation of the individual fractions obtained from

Table 1. BASE COMPOSITION OF FOOT-AND-MOUTH DISEASE VIRUS RNA

Individual fractions from gradients were precipitated with 1 mg yeast RNA and hydrolysed in 0.3 N potassium hydroxide for 18 h at 37°. The 2'-3'-nucleotides were separated by paper electrophoresis at pH 3.5 in sodium citrate buffer. The distribution of phosphorus-32 in the ultra-violet absorbing regions was determined after elution.

sucrose gradients. For the determination of the base composition, aliquots of each fraction were precipitated with 2 volumes of ethanol at -20° following addition of purified yeast RNA. The precipitates were then hydrolysed in 0.3 N potassium hydroxide and the distribution of radioactivity in the 2'-3'-nucleotides was determined. Aliquots of individual fractions were precipitated with ethanol in the presence of unlabelled baby hamster kidney cell RNA, which was added to serve as an internal marker, and then recentrifuged in a second sucrose gradient. The results in Table 1 show that the RNA sedimenting in fractions 1–15 of virus-induced RNA has the same base composition as RNA extracted from purified virus^{10,11}. Recycling of the individual fractions showed, however, that peak A was not homogeneous but consisted of a spectrum of fractions which differed in their sedimentation coefficients (Fig. 2B, C, D). In contrast, different fractions of the RNA from purified radioactive

Fig. 3. Sedimentation in sucrose gradients of RNA from purified ³²P-labelled FMD virus. Unlabelled BHK cell RNA was added to each sample before centrifuging to serve as an internal marker.

virus obtained in a similar way by sedimentation in a sucrose gradient had the same sedimentation coefficient (Fig. 3). The spectrum of sedimentation values present in virus-induced RNA has therefore been interpreted as being due to molecules of different chain-lengths. It is considered unlikely that these differences in sedimentation values, which are not found in RNA from purified virus isolated by the same procedure, are due to the presence of different stable configurations. The results in Figs. 2 and 3 also reveal that peak A from virus-infected cells sediments more quickly than the RNA isolated from purified virus. This suggests that the RNA isolated from virus-infected cells contains some molecules which are larger than those which are incorporated into the virus particles. These molecules, as shown in Table 1, have the same base composition as virus RNA. Molecules of a length greater than that of virus RNA could not be formed on the basis of the displacement mechanism shown in Fig. 1. The maximum length that could be obtained by this mechanism would be the same as that of the primer RNA.

We have also examined the structure of the ribonuclease-resistant RNA obtained by two successive centrifugations in sucrose gradients of virus-induced RNA which had been treated with 0.01 μ g RNase/ml. This has a base composition which is in agreement with its being a duplex structure consisting of a plus and a minus strand (Table 1). Heating this molecule at various temperatures up to 110° C for 5 min, followed by rapid cooling, has failed to produce any molecules sedimenting at the same position as virus RNA (peak A, Fig. 3). A typical result is shown in Fig. 4, which indicates that both heated and unheated RNA sediment in approximately the same position. Nevertheless, after heating at 110° C the ribonuclease-resistant RNA is degraded by the enzyme. Single-stranded RNA isolated from purified virus also sedimented to the same position as the ribonuclease-resistant RNA after

Fig. 4. Effect of heating at 110° in 10⁻³ M EDTA on the sedimentation in sucrose gradients of RNase-resistant RNA and virus RNA. (A), Unheated RNase-resistant RNA; (B), heated RNase-resistant RNA; (C), without RNase; (D), heated virus RNA.

Fig. 5. Diagrammatic representation of the proposed model for virus RNA replication

heating under these conditions (Fig. 4C). Apparently, heating single-stranded virus RNA in this manner produces structural or configurational changes in the molecule which are sufficient to greatly reduce its sedimentation coefficient. The fact that heating the ribonuclease-resistant RNA at 110° C did not produce any molecules with sedimentation coefficients smaller than that of heated virus RNA has been taken as evidence for the absence of a double-stranded structure in which the plus strand is composed of segments (cf. Fig. 1b).

All the evidence at present available leads us to propose a replicating form which will release an intact double strand on ribonuclease treatment and also permit the synthesis of molecules with different chain-lengths. Neither of these requirements can be met with the displacement mechanism at present held. It is postulated that the ingoing virus RNA (plus strand) codes for a complementary minus strand (Fig. 5). This minus strand takes up the configuration of a circle, or is synthesized as a cyclic structure. The RNA polymerase which produces the new plus strands can rotate around this cyclic primer producing a long chain of plus strand, which is repetitive in sequence. This long chain is then broken down by an enzyme into segments of approximately the correct length for viral RNA. Molecules of shorter length may function as specific messenger RNAs for the synthesis of virus coat protein. This may be the function of the molecules present in peak B of the virus-induced RNA. Only those molecules of the correct length are finally incorporated into virus.

This cyclic replicating form is consistent with the evidence available at present. On ribonuclease treatment the side chain will be removed and the ring probably opened at the growing point to yield a complete double strand. The hypothesis also explains the presence of virus-like RNA in virus-infected cells that has longer chain-lengths than the RNA extracted from purified virus.

CYTOPLASMIC ORGANELLES AND CELL GROWTH IN ROOT CAPS

By DR. B. E. JUNIPER and DR. F. A. L. CLOWES

Botany School, University of Oxford

CELLS are the products of expansion and division of other cells, and so mechanisms must exist for the division or the production *de novo* of cytoplasmic organelles to compensate for increase in the size and the number of cells. There are many references to possible mechanisms for the duplication or origin of cytoplasmic organelles, but no direct visual study has been carried out on their numbers in relation to cell growth and development of a homogeneous plant tissue.

We have chosen the cells of the root cap for the investigation recorded here because they lack large vacuoles, and this makes it easier to produce good estimates of the numbers of cytoplasmic organelles. The cells at the periphery of the cap contain small vacuoles, but they do not possess the single large vacuoles of other kinds of differentiated plant cells. In *Zea mays*, and the Gramineae generally, the cap is clearly demarcated from the rest of the root by a thick cell wall which we shall call the cap junction. In *Zea* the meristematic cells of the root cap, those nearest to the cap junction, cut off cells distally, approximately once every 12 h, and are the most rapidly dividing cells of the root. Meristematic activity ceases within 100 μ of the cap junction, and the cells expand from this point onwards, only ceasing to do so at the periphery where they are sloughed off. Along the axis of the cap in the primary roots of *Zea* there are approximately sixteen cells in this developmental sequence from initiation to detachment; the length of the root cap is about 450 μ and the overall increase in cell size is fifteen-fold. We shall consider only a column of non-vacuolate cells, extending from the distal side of the cap junction to a region one or two cells proximal to the very tip of the root. Median longitudinal sections through this zone have provided the material for the counts of organelles. The organelles that have been counted and measured are the mitochondria, the Golgi bodies, the plastids and the endoplasmic reticulum (ER). The first three have been counted and measured and the area of the ER has been calculated from the length of the profiles in the sections.

The techniques for embedding, sectioning and photographing large sections of plant tissue have already been described⁷. Complete mosaics of the cap tissue corresponding to a region about 400 μ long by 100 μ wide have been assembled. Such an area of a median section includes practically all of the cells of the cap that are non-vacuolate. The cap junction has been used as a base line and quadrats corresponding to 1,500 μ^2 of tissue have been marked off successively until the tip of the cap is reached. The numbers of organelles and length of ER have then been counted within each quadrat. We have assumed that the sections were a constant 50 μ thick and that the depth of focus of the microscope was greater than this. Allowances have been made for the variation in the size of the organelles by calculating the numbers of sections occupied by organelles of average dimensions at every level along the cap. The results have been expressed first on a per unit volume of cytoplasm basis after making a correction for the volumes of nuclei and secondly on a per cell basis using average cell dimensions at a range of levels in caps of similar size to estimate cell volumes and cytoplasm volumes. The amount of ER is given as an area, on the assumption that each profile seen in the electron micrographs is a section through a sheet of ER as wide as the thickness of the section.

Figs. 1 and 2 show the results from one single root cap mosaic. The results of two other complete mosaics have been compared and are, in all important respects, identical. However, root caps vary in length so that averages conceal trends.

The most striking feature of the quantities per cell is the difference between the numbers of the plastids on the one hand and the mitochondria, Golgi bodies and ER on the other. The number of plastids per cell varies very little, about three-fold, whereas the numbers or quantity of the other three components are more nearly constant per unit volume and therefore vary about 15-fold on a per cell basis. This means that the production of most, if not all, of the plastids probably takes place in the dividing cells, although growth of each individual plastid continues in the enlarging cells. On the other hand, the division or production of the other components takes place not only in the dividing cells but also in all the cells of the root cap.

Fig. 1. Average numbers of organelles and areas of endoplasmic reticulum per unit volume of cytoplasm (log scale) at various levels along the length of the root cap of *Zea mays*. Levels near the cap junction include the meristematic cap initials and those beyond 400 μ are the peripheral cells at the tip of the root.

Fig. 2. Average numbers of organelles and areas of endoplasmic reticulum per cell (log scale) at various levels along the length of the root cap of *Zea mays*.

Although the numbers or amount of the components other than the plastids increase as cell expansion proceeds, they do not all appear to keep pace with the increase in cell volume. Only the ER maintains its level per unit volume, whereas both the mitochondria and the Golgi bodies fall in numbers per unit volume during the early phase of cell growth to approximately half the quantity found in the meristematic cells. In both, however, the total per unit volume in the peripheral cells is practically identical to the total in the meristematic cells. Our interpretation of this fall is that the rates of reproduction of the mitochondria and the Golgi bodies do not quite keep pace with cell expansion at first but recover their original concentration per unit volume as cell enlargement slows and ceases.

The ER maintains its level per unit volume, or even may increase it slightly throughout the changes which each cell undergoes in rates of division and growth. This contrasts with the subjective impression gained from the electron micrographs of sparsity in the meristematic cells and abundance in the peripheral cells. In the meristematic cells the profiles of the ER are short and irregularly dispersed; in the cells from 100–300 μ from the cap junction the profiles of the ER are longer and they are most often distributed parallel to the cell wall and to the nuclear membrane; in the peripheral cells the profiles remain long but form irregular rings and loops with no obvious orientation. This feature of the peripheral cells, a property of ordinary roots, is similar to the distribution of the ER described by Bouček⁴ as a product of centrifugation.

The mechanisms of origin and division of cytoplasmic components are still subjects for dispute. There is evidence, for example, for the *de novo* origin of the mitochondria^{2,6,11} and of the plastids³. There is, however, rather more evidence for the view that both mitochondria and plastids always arise by fission except perhaps in special cells. This evidence comes from electron microscopy^{9,10,15,16}, from light microscopy¹⁷ and from the radioactive labelling of mitochondrial structural precursors in *Neurospora*^{13,14}. In the latter the distribution of the labelling is consistent with fission rather than *de novo* origin. We have no evidence in this tissue for any method other than fission for the origin of mitochondria and plastids. Many electron micrographs show images consistent with such a process for the plastids in the meristematic cells and for the mitochondria in both the meristematic and enlarging cells.

The exact mechanism of the sub-division of the Golgi bodies is not known and it may well be that a number of systems operate. The number of cisternae of each Golgi body in this tissue varies from two to seven and this suggests that the division of the Golgi could be brought about by the separation of the cisternae. An alternative mechanism, proposed by Buvat⁸ for Golgi division in the leaves of *Elodea canadensis*, and illustrated by convincing

micrographs, is the division of a Golgi body at right angles to the planes of the cisternae. But we have not observed any images which would be consistent with such a mechanism in this tissue. If a cisternal separation (as opposed to a cisternal sub-division) mechanism were to operate, the multiplication of new cisternae could follow by some process similar to the formation of multiple membrane stacks from the nuclear membrane noted by Barer *et al.*¹.

The origin of the ER is even more difficult to understand. Lindgren¹² has suggested that in yeast the ER is assembled within the nucleus and fed through the nuclear membrane via an 'extruder duct'. Barer *et al.*¹, in animal tissue, have suggested a mechanism in which blebs from the nuclear membrane are converted either into flattened cisternae or annuli and thence migrate into the cytoplasm. We have no evidence in this tissue for either of these processes, but there is nearly always some ER lying close to the nuclear membrane in the expanding cells.

We have demonstrated that plastids differ in their pattern of division from the three other cytoplasmic components considered. The mitochondria, Golgi bodies and ER appear to be closely correlated with cell size. However, it is not only numbers of organelles that are significant when we come to study metabolism. Size and differentiation of the organelles may also be important. It is well known that the development of the cristae of mitochondria varies during differentiation of the cell and generally cristae become more prominent in metabolically active cells¹⁸. The size and shape of the Golgi bodies also vary considerably^{7,16,19}, possibly in relation to carbohydrate metabolism. Moreover the plastids, although remaining few in number per cell, increase their volume sixty-fold within 300 μ from the cap junction. Therefore the estimates of numbers of plastids, mitochondria and Golgi and area of ER presented here should be considered in conjunction with changes of size and differentiation of each kind of organelle.

THE BURSA PHARYNGEA IN THE GIANT PANDA (*Ailuropoda melanoleuca*)

By PROF. A. J. E. CAVE

Department of Anatomy, St. Bartholomew's Hospital Medical College, London, E.C.1

THE bursa pharyngea, first described in man by Mayer¹, occurs in foetal and young mammals as an insignificant, single, dorso-medial recess in the mucosa of the epipharynx below the basioccipital: in the adult it is often less readily detectable, or even wanting. Killian² summarized the early knowledge of this structure and examined it in a representative range of foetal and post-natal material, both human and mammalian: he showed it to be the centre of a specialized mucosal arrangement associated with the peculiar aggregation of mucous glands and lymphoid tissue known as the tonsilla pharyngea.

The morphology of this structure has, not unnaturally been most intensively studied in the human subject, and detailed accounts of its gross and microscopic anatomy therein have been provided by Symington³, Joannesco⁴ and others.

While there is general agreement that the mammalian bursa pharyngea is without developmental relationship either to the cranio-pharyngeal canal or to the cranial extremity of the notochord, no specific function has been attributed to it. It is invariably situated underneath the occipital component of the basis cranii and immediately

above the muscular roof (m. palatopharyngeus) of the true (oro-)pharynx; it is thus a minute posterior mucosal diverticulum of that respiratory chamber which lies behind the nasal fossae and above the pharynx proper, which is most aptly termed the epipharynx. It would appear that, in some mammals at least, the commonly insignificant bursa pharyngea may develop into an epipharyngeal diverticulum of gross, dissectable size, and the existence of such diverticula in bears has long been known, their presence having been reported (by Mayer¹, Rapp², Alix³ and Boulart⁷) in *Ursus arctos*, *U. americanus*, *U. horribilis*, *Melursus ursinus* and *Helarctos malayanus*. Such ursid diverticula are, however, dual structures of unequal size. Thus Alix³, in *Melursus ursinus*, found the dextral diverticulum to be 5 cm long by 3 cm wide, the sinistral diverticulum only 2 cm long by 0.5 cm broad. Such paired epipharyngeal diverticula appear to be confined to the Ursidae, for Killian² failed to observe any comparable structures in a variety of carnivores (*Canis familiaris*, *Nasua rufa*, *Viverra civetta*, *Herpestes griseus*, *Paradoxurus trivirgatus*, *Mephitis mephitis*, *Felis domestica*, *Lutra vulgaris*), and recently Davis⁴ has noted their absence in *Procyon lotor* and *Ailurus fulgens*. Davis did, however, observe the presence of a pair of unequal bursae pharyngeae in a sub-adult (16 months old) male specimen ('Sun Lin') of the giant panda, *Ailuropoda melanoleuca*, and regarded this finding as additional evidence indicative of the ursid rather than the procyonid nature of this form.

In this immature animal the dextral, larger sac had a slit-like orifice some 7 mm long, a narrow neck and a capacious body: it measured 130 mm in length by 30 mm in maximal breadth and its fundus was partially subdivided by a short septum; the smaller sinistral sac was only 15 mm long. Both sacs were thin-walled, with a longitudinally plicated lining. The larger sac extended caudally dorsal to the pharynx and the anterior oesophagus and ventral to the basioccipital and the bodies of the anterior five cervical vertebrae.

In 1939, during the post-mortem examination of the first *Ailuropoda* specimen to die in the London Zoo (the adult female animal 'Grandma'), I observed an obtrusive patch of thin, reddish-brown, mucous membrane clothing the under surface of the basioccipital region and extending caudally over the anterior cervical vertebral bodies between the bilateral eminences of the powerful longus colli muscles. Though the cut edge of this membranous patch was unmistakable, its connexions were not then ascertainable; it was therefore recorded as something unusual and possibly of a pathological nature. The subsequent examination of additional *Ailuropoda* specimens, however, made it clear that this curious mucosal patch was nothing other than the adherent dorsal parietes of an unidentified epipharyngeal diverticulum (enlarged bursa pharyngea) mutilated during necropsy.

In 1944, the adult (7 years old) female giant panda 'Ming' died in the London Zoo and in 1950 so did the 6-year-old male animal, 'Lien Ho'. By courtesy of the Council of the Zoological Society of London the throat parts of these two animals became available for anatomical examination. In each specimen a well-developed enlarged pharyngeal bursa was present in the shape of a single, median, thin-walled, piriform sac, presenting ostium, neck, body and fundus. In each specimen this sac lay between the basi-occipital and anterior cervical vertebrae dorsally and the pharynx and anterior oesophagus ventrally: to the former structures the dorsal sac wall was firmly adherent; to the latter the ventral sac wall was only loosely attached by blood-vessels and connective tissue.

The rounded ostium, some 6 mm in diameter, opened from the epipharynx immediately above the arcus palatopharyngeus: the sac neck was approximately 30 mm long and was longitudinally plicated interiorly; the sac body measured approximately 55 mm long by 28 mm in maximal width; the sac fundus overlay the

beginning of the oesophagus. The sacs of the two animals agreed in all anatomical particulars and their morphological nature could not be in doubt; they represented a particular and remarkable development of the otherwise insignificant bursa pharyngea (Figs. 1 and 2).

It is curious that in Davis's young male *Ailuropoda* specimen (as in bears), two enlarged pharyngeal bursae of unequal size should have been present, whereas both in the adult male and in the adult female specimen

Fig. 1. *Ailuropoda melanoleuca* (giant panda) adult female. Dorsal aspect of pharynx with opened bursa pharyngea in situ. White rod in bursa ostium, dark rod at junction of neck and body of bursa

Fig. 2. *Ailuropoda melanoleuca* (giant panda) adult male. Dorsal aspect of pharynx with bursa pharyngea in situ: short transverse rod in opened bursa neck, longer transverse rod between bursa and pharynx, vertical rod traversing sac body

examined by me, only a single bursa should occur. The range of variation of this bursa cannot, however, be known until a wider range of *Ailuropoda* material has been investigated. There is, nevertheless, no doubt as to the morphological identity of these epipharyngeal diverticula, for, whether manifested as single or as dual structures, their topographical relationships are identical.

The occurrence of a comparably developed pharyngeal bursa is not recorded for non-carnivores. This may well be because of the rarity of suitably fixed material for specific investigation and because of the inevitable damage inflicted on the pharyngeal region during routine post-mortem examination.

I myself have evidence, however, of the occurrence of a large, single epipharyngeal diverticulum (enlarged bursa pharyngea) in mammals outside the order Carnivora. For in the excised pharynges of an adult male and an adult female white rhinoceros (*Ceratotherium simum*), of an adult Indian rhinoceros (*Rhinoceros unicornis*), of an adult okapi (*Okapia johnstoni*) and of a young giraffe (*Giraffa camelopardalis*), the dorsal aspect of the pharynx has, loosely attached to it, some portion of the ventral moiety of a mutilated but unmistakable pharyngeal bursa, the absent portion of which has remained adherent to the skull base and anterior cervical spine (Figs. 3 and 4). These (imperfect) diverticula are thin-walled, bluntly piriform sacs, communicating anteriorly with the epipharynx above the arcus palatopharyngeus; their narrow necks are succeeded by expanded bodies and their fundi overlie the anterior portion of the oesophagus. Histological examination of

Fig. 4. *Giraffa camelopardalis* (giraffe) juvenile female. Dorsal aspect of soft palate and pharynx, with remnant of ventral wall of bursa pharyngea in situ.

Fig. 3. *Ceratotherium simum* (white rhinoceros) juvenile male. Dorsal aspect of pharynx showing in situ (and separated by white card) remnant of ventral wall of bursa pharyngea.

their longitudinally plicated mucosa reveals a typical (that is, pseudo-stratified columnar ciliated) epithelium, an abundance of mucous (or muco-serous) glands, often opening into distinct crypts, an extraordinarily rich, specialized vasculature and an intense infiltration of mucosa and submucosa by lymphoid tissue manifesting germinal centres. A detailed account of these non-carnivore pharyngeal bursae will be published elsewhere.

The presence or absence of specialized pharyngeal bursae in mammals generally merits further investigation, as does the precise physiological role of the bursae themselves.

The general function of the mammalian epipharynx is partly mechanical (the reception of conditioned air from the nasal fossae) and partly defensive, since therein the inspired air is brought into particularly intimate contact with an abundance of highly active, protective lymphoid tissue. The elaboration of the customary bursa pharyngea into a single or double posterior diverticulum of some magnitude doubtless enhances the defensive role of the epipharynx, but it remains to be explained why such diverticula should be developed in some mammalian forms and yet be wanting in others.

ELECTRON MICROSCOPE OBSERVATIONS ON THE FREE PROTEIN AND THE PROTEIN-POLYSACCHARIDE COMPLEX OF BOVINE SYNOVIAL FLUID

By DR. JAMES W. SMITH and DR. JOHN FRAME

Department of Anatomy, St. Salvador's College, University of St. Andrews

THE two major constituents of synovial fluid are hyaluronic acid and soluble protein: in the ox, the average concentration of hyaluronic acid is about 0.05 g per 100 ml.¹, while that of soluble protein is about 0.9 g

per 100 ml.². The protein fraction is entirely derived from the blood serum^{3,4}. The hyaluronic acid exists in large measure as the sodium salt, and this sodium hyaluronate is bound to a part of the soluble protein as a

hyaluronate-protein complex⁶. Although the existence of this complex is generally accepted, little is known of its nature: assessments of the amount of protein which the complex contains have varied from 30 per cent⁶ to 2 per cent⁷, and little is known of the manner in which the two parts of the complex are combined.

When synovial fluid is acidified to pH 3 with acetic acid, a mucin clot forms and can be readily separated from a clear supernatant fluid⁸. The supernatant contains a proportion of the protein of the synovial fluid⁸, and very little, if any, of the hyaluronate-protein complex¹. The mucin clot thus certainly contains the greater part of the complex but its content of free protein is controversial. Free protein can be separated from the clot by various means^{7,9}, but opinion varies as to whether this is to be regarded as a separation of distinct compounds or a degradation of the complex.

It was considered that a new approach to this problem might be made by electron microscopic examination of synovial fluid and its mucin and supernatant fractions after suitable precipitation and staining. The use of lead salts for the fixation of acid mucopolysaccharides was introduced for conventional histology by Holmgren and Wilander¹⁰, and various modifications of their method are now in use. Lead salts have also been used in the past few years as stains which enhance the electron-scattering properties of biological material¹¹⁻¹³.

It is well known that the sodium ion with which hyaluronic acid is normally associated in the tissues may be exchanged for other cations, the extent of the exchange depending on their concentration and valency^{5,14,15}. This type of exchange is utilized in Hale's stain¹⁶ and in the precipitation of hyaluronic acid by hexavalent cobalt salts⁵. When 1 per cent lead nitrate is added to an equal volume of 0.1 per cent potassium hyaluronate or hyaluronic acid (B.D.H.), a fine off-white precipitate forms immediately and can be spun down into a discrete pellet. On the addition of potassium nitrate the precipitate disappears. It is considered that this precipitate is insoluble lead hyaluronate.

At acidities of pH 3-7 small amounts of lead ions cause almost complete precipitation of comparatively large amounts of protein from solution¹⁷. Single lead ions are bound to individual carboxyl groups of the protein¹⁸ and the reaction, which is reversible, is complete within an hour. It is considered, therefore, that lead nitrate causes precipitation of both hyaluronic acid and soluble proteins.

In the present investigation, therefore, synovial fluid was separated by acidification into mucin clot and supernatant. The clot was washed in acetic acid and then in distilled water, and afterwards redissolved in water at pH 10. The reaction of this solution, and that of the supernatant, was adjusted to pH 7.5. Synovial fluid, the mucin clot solution and the supernatant fractions were then fixed and stained by the addition of equal parts of 1 per cent lead nitrate and 10 per cent neutral formalin at pH 5. With synovial fluid a discrete coagulum was formed, while with the two fractions diffuse precipitates were produced and were afterwards spun down into pellets. The coagulum and pellets were then dehydrated and embedded in 'Araldite', and sections were examined, without further staining, in a Siemens Elmiskop I microscope.

Fig. 1 shows the appearance in the light microscope of a thick 'Araldite' section of synovial fluid, stained with toluidine blue. The field is occupied by small particles of varying densities. Most appear to be approximately spherical and many are linked together to form short linear groups.

In the electron microscope, thin sections of the same material exhibit the appearance shown in Fig. 2. It is now apparent that the particles are irregular in shape and, as would be expected, the linear groupings, though still evident, are less frequent. All the larger particles

contain two distinct materials, a central group of dark (or electron dense) spherical bodies which vary in diameter from 300 to 1200 Å, being surrounded by a larger volume of lighter (or less dense) material. The particles which do not exhibit central dark bodies are always small, and this is consistent with the view that the dark bodies are a feature of all particles and that their apparent absence from some is due to tangential sectioning. On the other hand, dark bodies have not been observed without the enveloping lighter material.

In Fig. 3 the supernatant fraction is seen to consist predominantly of dark spherical bodies similar in both size and density to the central dark bodies in synovial fluid particles. In addition, there are a few areas which consist of lighter material, which has an appearance reminiscent of the peripheral material in synovial fluid particles. As has been noted, the supernatant contains a proportion of the original protein content of the synovial fluid and very little, or possibly none, of the hyaluronate-protein complex¹. On this basis it seems reasonable to postulate that the dark bodies in Fig. 3—and by virtue of their similar appearance the central dark bodies in synovial fluid particles (Fig. 2)—are aggregates of free protein molecules. In a very thin 'Araldite' section of the supernatant material (Fig. 4) it is indeed evident that the dark bodies in Fig. 3 are aggregates of smaller rod-like units and the dimensions of these are of the same order as the calculated dimensions of the molecules of albumin and γ -globulin¹⁹⁻²¹.

The appearance of the washed mucin fraction is shown in Fig. 5. It is evident that it is morphologically very similar to the peripheral light material of the synovial fluid particles (Fig. 2), exhibiting the same density and the same irregular outline. Moreover, the absence of dark bodies comparable with those in the synovial fluid particles (Fig. 2) and the supernatant fraction pellet (Figs. 3 and 4) appears to be absolute. It seems reasonable to conclude, therefore, that the washed mucin clot contains no free protein, and consequently that both the washed mucin clot and the peripheral light material in synovial fluid particles consist entirely of hyaluronate-protein complex.

As a result of the present investigation, it is considered that in sections of the coagulum formed by treatment of synovial fluid with lead nitrate, free protein and hyaluronate-protein complex are both visible in distinct

forms. The coagulum consists of particles, variable in diameter, joined together as a continuous network by thinner strands. Each particle contains a variable number of dark central spherical masses which are considered to be aggregates of free soluble protein molecules. These are surrounded by a lighter sponge-like mass of hyaluronate-protein complex which is continuous from particle to particle through the thin connecting strands. It is presumed that the different degrees of electron-scattering exhibited by the soluble protein, on one hand, and the hyaluronate-protein complex on the other, are to be related to differences in the amounts of lead bound to the two substances.

In the natural state, of course, both the complex and the free protein are much more dispersed, and the condensation of both moieties into an isolated network is an artefact produced by precipitation. Indeed, such an alteration from a dispersed state to a condensed network seems to be typical of the action of any coagulant fixative^{22,23}. The change involves both the binding of adjacent molecules to one another and the formation, in certain situations within the tissue, of planes of cleavage on either side of which condensation occurs in opposite directions. In synovial fluid particles the dark, free protein bodies almost invariably lie centrally and never occur without a covering of hyaluronate-protein complex. One possible explanation is that in untreated synovial fluid the free protein molecules and the complex are not evenly mixed but are preferentially situated in separate zones, and that, on fixation, condensation of both fractions takes place with the planes of cleavage occurring always through zones occupied by complex.

It was noted earlier that the composition of the hyaluronate-protein complex of synovial fluid is still highly controversial. Ogston and Stanier⁶ showed that although the mucin clot formed on acidification of synovial fluid contained entrained free protein, after washing, first in 1 per cent acetic acid and then in distilled water, the weight of the clot reached a constant value. It then contained about 70 per cent hyaluronic acid and 30 per cent protein. It was further demonstrated that the residue, obtained after filtration of synovial fluid through sintered

glass filters, which allowed the passage of free protein, again contained between 30 per cent and 25 per cent of protein^{6,24}. These authors considered that any reduction in this amount of protein was to be regarded as a degradation of the complex rather than a purification by removal of free protein. More recently, it has been suggested^{7,9} that the amount of protein actually combined to hyaluronate is considerably less, being of the order of 2 per cent, and this view has been rather widely accepted²⁵⁻²⁷. The results of the present investigation are in keeping with the older view of Ogston and Stanier. The morphology of the washed mucin clot suggests that it contains no appreciable amount of free protein and is to be regarded as identical with the hyaluronate-protein complex.

POSSIBLE RELATIONSHIP BETWEEN TRACE METALS AND BLOAT IN RUMINANTS

By P. J. HARRIS and PROF. F. SEBBA

Department of Chemistry, University of the Witwatersrand, Johannesburg, South Africa

FROTHY bloat occurs in ruminants when they are fed green lucerne or similar lush green fodder. It is due to the formation in the rumen of a froth of remarkable toughness and stability. This froth builds up inside the rumen, owing to the entrapped gases produced during bacteriological fermentation of the feed, until it rises above the level of the reflex mechanism and prevents eructation. Death usually follows from internal pressure on the vital organs lying close to the rumen. Plant proteins, saponins and bacterial polysaccharide and peptide slimes have severally been suggested, singly or in combinations, as the cause of this stable foam. Nothing is known concerning the critical conditions under which they may become foam-formers in the rumen, nor the part, if any, which each plays in the formation of the foam. Further understanding of this problem requires an investigation of the physical and chemical properties of the surface-active agents in green lucerne with particular reference to their ability to produce tough foams. Investigations of this kind have been started at this university,

and the following preliminary results suggest a new approach to the problem.

Traces of metal hydroxides and, in some cases, metal cations have been shown to affect the stability of foams. Lucerne extracts were made up in a sodium bicarbonate buffer to simulate the pH conditions inside the rumen, and by bubbling air through such solutions, and polarographic examination of the foam fractions, traces of nickel and zinc were found to have been concentrated in the foam.

The foam fractionation apparatus (Fig. 1) consisted of a large foaming vessel 3.5 in. in diameter and 12 in. in height with a sintered glass disk of porosity 4 sealed into the base. A glass ring 1.5 in. in length and of the same diameter as the foaming vessel was placed on top of it. Air was bubbled through the solution at a fixed rate, and at the appropriate time a thin copper metal sheet was slid between the vessel and the ring. The foam fraction was thus retained inside the ring and could be removed for analysis. An identical clean ring was immediately placed on top of the vessel to collect the next fraction of

foam. Samples could be obtained every 30 sec and were prepared for polarography using the method of Reed and Cummings¹. The sample was ashed below 500° C, treated with concentrated hydrochloric acid and evaporated to dryness. The residue was taken up in dilute hydrochloric acid and adjusted to pH 4.6 using a glass electrode. The solution was then filtered to remove any aluminium and iron present and evaporated to dryness. The residue was afterwards dissolved in 10 ml. of a solution of 0.1 N ammonium acetate, 0.025 N with respect to potassium thiocyanate and of pH 4.6. This solution was examined polarographically at a mercury electrode dropping at a rate of 1 drop every 1.8 sec.

Samples of lucerne from two different sources were used:

(a) Fresh green lucerne was obtained from a Johannesburg City Council farm. One portion was extracted immediately and the juices diluted 10 times in a 0.5 per cent sodium bicarbonate buffer of pH 4.5 before foaming. The second portion was allowed to dry and age for 2 weeks before extraction and dilution of the juices in the same manner.

(b) A sample of fresh lucerne, grown in a hot-house at the University of the Witwatersrand, was extracted and diluted 10 times in the sodium bicarbonate buffer. One-half of the solution was immediately foamed, while the other half was kept at 4° C for 6 days before being foamed.

In both cases the foaming rate was maintained constant at a fixed rate.

In order to examine the stabilities of the foams, a foam drainage apparatus was used, based on that of Ruysen and Louwers² (Fig. 2). The liquid in the vessel was foamed by bubbling air through a small sintered glass disk of porosity 3 at a constant rate. As the foam was formed, the decreasing level of liquid was periodically re-adjusted to its initial height by the addition of liquid from the burette. During the drainage of the foam the liquid level was kept constant by draining off the liquid at definite time-intervals. This permitted the determination of the total volume of liquid in the foam as a function of time.

Sample (a). The decrease in stability of the foam formed from the aged lucerne in comparison with that formed from the fresh lucerne was very noticeable. The foam

Fig. 2. Foam drainage apparatus. A, Foam drainage vessel; B, burette; C, sintered glass disk

Fig. 1. Foam fractionation vessel. A, Glass ring; B, foaming vessel; C, solution; D, sintered glass disk

from the aged solution was too unstable to give reasonable measurements using the foam drainage apparatus. The foam fractions obtained from these two solutions were examined polarographically for nickel and zinc. During the first 10 min of foaming the concentration of nickel in the foam fractions from the fresh lucerne was five times greater than the nickel concentrations in the foam from aged lucerne (Fig. 3). Similarly, although not so marked, the zinc concentrations were higher in the foam than in the very much more stable fresh lucerne solution (Fig. 4).

Sample (b). The difference in stability between the foams of the fresh lucerne solution and the solution which was allowed to stand for 6 days was checked using the foam drainage apparatus. During the actual foam fractionation, samples of the solution were removed at definite time-intervals and these were used for measurements of drainage rate. In Fig. 7 it can be seen that there was a definite decrease in the stability of the foam formed from the 6-day-old solution. On examination of the nickel concentration in the foam fractions it was found that the

nickel content had decreased slightly in the older solution (Fig. 5) while the zinc concentration had remained more or less the same (Fig. 6).

The overall patterns of the nickel and zinc concentrations in the foams are different for the two samples. This is possibly due to the different soils in which the plants were grown and the different fertilizers used. In each case a decrease in stability of the foam has been accompanied by a decrease in the nickel concentration in the foam. In the solution of fresh lucerne the nickel had been concentrated in the foam whereas in a solution which formed an unstable foam the nickel concentration in the foam was very much the same as that in the solution. The concentration of nickel in the solution was approximately 3×10^{-7} g/ml. and in a stable foam this increased to nearly 15×10^{-7} g/ml. The highest concentrations of nickel were found in the first four foam fractions only, and from Fig. 7 it can be seen that the stability of the foam decreased with time.

Examination of the nitrogen content of the foam fractions of fresh lucerne by the Kjeldahl method showed an increase in nitrogen in the first foam fractions. This indicates that the surface-active agent is initially a protein. It is presumed that it is the negatively charged sites on the protein which combine with the positive nickel ions. This would well be a naturally occurring example of ion flotation in which the protein acts as collector and the metal ion is collected³. In the fresh lucerne the nickel appears to be available for attachment to the protein, while in the aged lucerne, although it is still present, it is no longer in an available form. This has been verified in preliminary experiments where small traces of nickel sulphate added

Fig. 4. Sample 1. Concentration of zinc in foam versus time. —, Fresh lucerne solution; ---, aged lucerne solution

Fig. 6. Sample 2. Concentration of zinc in foam versus time. —, Fresh lucerne solution; ---, 6-day-old lucerne solution

Fig. 7. Stability (vol. of liquid after draining for 10 min) of foam versus time after foaming commenced. —, Fresh lucerne solution; ---, 6-day-old lucerne solution

to aged, and therefore unstable, lucerne solutions immediately caused a substantial increase in the stability of the foam from this solution. Initial tests show that the alkali metals have no measurable effect when added to aged lucerne solutions, nor has manganese, but zinc increases the stability slightly. However, none of these is nearly so effective as nickel in increasing the stability of the foam.

It may be surprising that the element nickel, which is not a usual trace metal in plants, should be found in lucerne. It should be pointed out, however, that the quantity present in the lucerne extract is barely detectable, and it is only when concentrated in the foam that its presence can be unequivocally confirmed.

It must be mentioned that foam drainage is not an ideal method for measuring foam stabilities, as drainage is not the only factor involved. A more refined and accurate technique than those available at present is required before the effects of various metal ions on the stability of the lucerne foam can be accurately measured. At present an apparatus is being developed here which, it is hoped, will give a more accurate measure of the factors determining foam stability.

We thank the Livestock and Meat Industry Control Board for financing this work, and Dr. F. M. C. Gilchrist, of the Veterinary Research Institute, Onderstepoort, for advice.

2,6-DIAMINO-3-HYDROXYPIMELIC ACID IN MICROBIAL CELL WALL MUCOPEPTIDE

By H. R. PERKINS

Twyford Laboratories, Twyford Abbey Road, London, N.W.10

THE diamino-acids hitherto identified in the cell-wall mucopeptide of various bacteria have been diaminopimelic acid, lysine and, more recently, ornithine and 2,4-diaminobutyric acid¹. Many years ago a species of *Micromonospora* (*LSTM*) was found to contain a component that moved slowly in paper chromatographic systems and gave with ninhydrin the same characteristic colour as diaminopimelic acid after chromatograms had been developed with methanol/pyridine/hydrochloric acid². Recently, examination of the cell-wall composition of many strains of *Actinomyces* showed that some members of the *Actinoplanes* and a strain of *Micromonospora* contained the same "slow-moving component"³. In particular, Yamaguchi³ reported that the cell walls of *Ampullariella regularis* contained glutamic acid, alanine, glycine and the "slow-moving component" with only traces of diaminopimelic acid.

A culture of *A. regularis* was obtained from the collection of Dr. J. N. Couch. The cells were grown and the cell walls were prepared as described by Yamaguchi³. After hydrolysis (6 N hydrochloric acid, 16 h, 105° C) samples were run on chromatograms in methanol/water/pyridine/conc. hydrochloric acid, 32 : 7 : 4 : 1 (solvent A). The dried chromatogram was treated with ninhydrin and heated. It showed the expected "slow-moving component", ($R_{\text{meso-diaminopimelic acid}} = 0.67$), giving with ninhydrin, like diaminopimelic acid, a greenish colour turning to permanent yellow. To recover larger quantities of this unknown component, 100 mg of dried cell wall was hydrolysed and the hydrolysate was run as a band on a sheet of Whatman No. 3 paper (previously thoroughly washed with 2 M acetic acid and then with water), in solvent B (methanol/water/pyridine/98 per cent formic acid, 80 : 19 : 10 : 1). This solvent was used instead of A to avoid contamination of the product with non-volatile pyridine hydrochloride. The "slow-moving component" gave $R_{\text{meso-diaminopimelic acid}} = 0.66$. The band was located by applying streaks of 0.025 per cent (w/v) ninhydrin in *n*-butanol at intervals across the paper. The unknown substance was eluted with water, the solution dried *in vacuo* and made up to a final volume of 0.2 ml.

A sample of the unknown substance subjected to paper electrophoresis at pH 7 in collidine acetate buffer⁴ gave a single neutral spot detectable with ninhydrin. The fact that the unknown ran slower than diaminopimelic acid in solvent A but gave a similar colour after ninhydrin treatment suggested that it might be a derivative with some neutral but polar substituent such as hydroxyl. If this hydroxyl were adjacent to one of the amino-groups, then the compound should be destroyed by periodate solution to yield glutamic semi-aldehyde and glyoxylic acid. On a similar basis 'tabtoxine', the amino-acid from the phytopathogenic toxin of *Pseudomonas tabaci*, was tentatively identified as 2,6-diamino-3-hydroxypimelic acid⁵. 1 μ l. of the solution of "slow-moving component" was treated with 2 μ l. of 0.2 M sodium periodate and 10 μ l. water at room temperature for 30 min. Then 2 μ l. of 20 per cent (v/v) ethylene glycol was added to destroy excess periodate. The mixture was spotted on Whatman No. 4 paper and run for 7 h in solvent B. Whereas an equal quantity of untreated material gave a clear ninhydrin-positive spot, the periodate had completely

destroyed the unknown substance. Confirmation of the destruction of the unknown substance by periodate was obtained by running two samples in solvent B, and spraying one with ninhydrin and the other with 0.5 per cent (w/v) sodium periodate followed after 5 min by benzidine in acetic acid/ethanol⁶. The white spot on a blue ground given by the second spray exactly corresponded with the ninhydrin-positive spot.

The overall length of the chain was confirmed by reduction as described by Stewart⁷. 5 μ l. of "slow-moving component" was sealed in a tube with a little red phosphorus and 0.2 ml. of freshly redistilled hydriodic acid, spec. grav. 1.7. The tube was heated at 120° for 8 h and then the excess acid was removed *in vacuo* and water added three times and similarly removed. The residue was dissolved in water and shaken with a small portion of cation exchange resin 'Zeo-Karb 225' (Na⁺). The resin was washed and then extracted with N ammonia solution. Ammonia was removed *in vacuo* and a sample of the extract run in solvents A or B gave clear spots of LL-2,6-diaminopimelic acid and meso-2,6-diaminopimelic acid (presumably mixed with the DD-form⁸). Similar racemization during reduction of synthetic diaminohydroxypimelic acid by hydriodic acid was observed by Stewart⁷. Thus the unknown was clearly a derivative of diaminopimelic acid, presumably hydroxylated.

The unknown substance was also degraded by permanganate. 4 μ l. of "slow-moving component" was heated at 60° C with 10 μ l. portions of 1 per cent (w/v) potassium permanganate in 20 per cent (v/v) sulphuric acid (five portions in all). The mixture was cooled and neutralized with saturated barium hydroxide solution. The concentrated supernatant gave, in addition to unchanged starting material, a spot corresponding to glutamic acid both on paper electrophoresis at pH 7 and on chromatography in solvent B. On the assumption that permanganate oxidized a secondary alcohol group to a carboxyl group, this result supported the suggestion from the periodate degradation that the compound had a hydroxyl group on C-3, an amino group at C-6 and a carboxyl group at C-7.

Racemic mixtures of the four possible pairs of optical antipodes of 2,6-diamino-3-hydroxypimelic acid have been synthesized and characterized^{7,9}, and crystalline samples of these substances were kindly supplied by Dr. John M. Stewart. Comparison of these substances with the unknown in solvent A gave the result shown in Table 1. It was evident that the unknown could only correspond to the slow component of either synthetic isomer B or isomer C. The fact that three of the synthetic substances gave more than one spot presumably meant that this solvent was capable of separating their optical enantiomorphs, just as it can separate DD- and LL-diaminopimelic acid⁸. The

Table 1. CHROMATOGRAM RUN ON WHATMAN NO. 1 PAPER IN SOLVENT A FOR 20.5 H

Spots revealed by ninhydrin	
Substance	$R_{\text{meso-diaminopimelic acid}}$
"Slow-moving component" from <i>A. regularis</i>	0.67
2,6-diamino-3-hydroxypimelic acid	
Isomer A	0.90
Isomer B	0.67, 0.81*
Isomer C	0.68, 0.91*
Isomer D	0.85, 1.01*
LL-diaminopimelic acid	1.16

* This compound gave two spots.

unknown was evidently not a racemic mixture but one of the optically active forms of isomer *B* or isomer *C*.

A further means of comparison of the unknown substance with diaminohydroxypimelic acid was offered by the reaction with ninhydrin at acid pH values, which gives characteristic absorption curves with diamino-acids¹⁰. Samples of the unknown, diaminohydroxypimelic acid isomer *B* and diaminopimelic acid, each in 0.5 ml. water, were heated with 0.5 ml. acetic acid and 0.5 ml. of ninhydrin reagent (2.5 per cent (w/v) ninhydrin in a mixture of acetic acid/0.6 M phosphoric acid, 3 : 2) at 100° C for 5 min. The mixtures were cooled immediately, diluted to 5 ml. with acetic acid and read in a colorimeter against a reagent blank. The absorption curves given in Fig. 1 indicate that the unknown substance from *A. regularis* is the same as 2,6-diamino-3-hydroxypimelic acid (maxima at 360 mμ and 420 mμ). The difference from diaminopimelic acid (maximum 345 mμ) is very marked.

Fig. 1 Absorption curves given in the reaction with ninhydrin at pH 0.9 (ref. 10) by: A, "slow-moving component" from *A. regularis*; B, 2,6-diamino-3-hydroxypimelic acid, isomer B; C, 2,6-diaminopimelic acid

Stewart⁷ found that conversion to the *bis*-dinitrophenyl derivatives provided the only sure way of separating the four isomers of 2,6-diamino-3-hydroxypimelic acid. Samples of isomers A, B, C, and D and also of the "slow-moving component" were converted to their *bis*-DNP derivatives⁷. They were then run overnight in solvent C⁷ (*n*-butanol/water/ammonia solution S.G.O.880, 20 : 19 : 1) giving the following values for R_{DNP} -isomer D: Unknown and DNP-isomer B, 0.51; DNP-isomer C, 0.84; DNP-isomer A, 0.94 (DNP-isomer D moved 21.2 cm). This result showed that the substance from *A. regularis* was isomer B and could not be isomer C.

Stewart⁷ observed that 'tabtoxinine' corresponded to one isomer of 2,6-diamino-3-hydroxypimelic acid when compared as the *bis*-DNP derivative, and to a different isomer when the free amino-acids were run on an ion-exchange column¹¹, indicating that it was not either of these substances. The "slow-moving component" was run in the EEL automatic amino-acid analyser on a 150-cm column of 'Amberlite CG 120' at 50° and in buffer at pH 3.25. It was eluted just before cysteine and in exactly the same position as isomer B of 2,6-diamino-3-hydroxypimelic acid. Mixtures of the two substances could not be separated, and furthermore the colours

developed with ninhydrin both gave the same ratio of extinction at 440 mμ compared with 570 mμ. This identity on column chromatography confirmed the previous results and allowed quantitative estimation of the composition of the isolated cell walls of *A. regularis*. The results are given in Table 2. They show that 2,6-diamino-3-hydroxypimelic acid is the only diamino-acid present in appreciable quantity in the cell walls of this *Actinomyces*.

Table 2

Component	Mole/10 ⁴ g	Molar ratio (muramic acid = 1)
Glucosamine	2.43	0.70
Muramic acid	3.49	1.00
Glutamic acid	3.79	1.08
Glycine	4.85	1.39
Alanine	2.43	0.70
2,6-Diamino-3-hydroxypimelic acid (isomer B)	2.78	0.80
Ammonia	2.53	0.67
2,6-Diaminopimelic acid	0.35	0.10
Lysine	0.1	0.03

Cell walls of *A. regularis* were prepared by breaking the organisms with glass beads, differential centrifuging, washing, extraction with 0.5 per cent (w/v) potassium hydroxide in ethanol (48 h 37°) followed by digestion with trypsin and pepsin⁸. The washed product was freeze-dried, and a sample hydrolysed in 4 N hydrochloric acid for 4 h at 105°. It was analysed on the EEL automatic amino-acid analyser.

No other amino-acid was present in a molar ratio greater than 0.17.

The identification of the "slow-moving component" in the cell walls of *A. regularis* as isomer B of 2,6-diamino-3-hydroxypimelic acid means that this substance can now be added to the list of diamino acids known to occur in the mucopeptides of microbial cell walls. From recently published surveys³ it is evident that the "slow-moving component" is present in several strains of *Actinomyces* and may clearly be of value in taxonomy. In this respect the value of the specific solvent and colour reaction of Rhuland *et al.*⁸ cannot be over-emphasized. Although the substance from *A. regularis* has been shown to be isomer B, it may be that the cell walls of other strains contain different isomers of diaminohydroxypimelic acid. Almost all these run more slowly than *meso*-diaminopimelic acid on chromatography (Table 1) and might well not have been distinguished by the methods so far applied⁸. Isomer B has the *threo* configuration for the vicinal hydroxyl and amino groups and the *meso* configuration for the two amino groups⁷. The fact that the racemic mixture gives two spots on chromatography (Table 1), only one of which corresponds to the substance from *A. regularis*, suggests that the natural compound will be optically active. It is not possible to say anything at present about its absolute configuration.

Stewart⁷ showed that the substance from *Pseudomonas tabaci* designated 'tabtoxinine'⁵ was not, in fact, identical with any of the four isomers of 2,6-diamino-3-hydroxypimelic acid. This is therefore the first time that this substance has been identified in natural products.

I thank Dr. J. N. Couch and Dr. H. Gooder for supplying the culture of *A. regularis*, Miss M. F. Leyland for assistance, Mr. V. Okoro for preparations of cell walls and Mr. M. W. C. Hatton for expertise with the automatic amino-acid analyser. I also thank Dr. John M. Stewart for samples of the four isomers of 2,6-diamino-3-hydroxypimelic acid.

HETEROGENEITY OF WATER-SOLUBLE STRUCTURAL COMPONENTS OF HUMAN RED CELL MEMBRANE

By PROF. M. D. POULIK and DR. P. K. LAUF

Child Research Center of Michigan, and Department of Pediatrics, Wayne State University School of Medicine, Detroit, Michigan

THE methods available for extraction of water-soluble mucoids adopt enzymatic¹ and chemical procedures. Phenol², phenol-water³⁻⁵, methanol-chloroform⁶ or ethanol extraction⁷ have also been used. To prepare protein components stroma has been extracted with ether (Soxhlet)⁸. This latter method is efficient and a number of protein components were separated in starch gel containing urea⁹. Unfortunately, such material is not water-soluble unless urea is present in the solvent. The application of *n*-butanol for extraction of enzymes from muscle tissues by Morton¹⁰ opened a new approach to the preparation of structural components of cells and biomembranes. Maddy¹¹ used this technique for the isolation of carbohydrate-rich proteins of ox red cell membranes. Harris¹² used a similar method for the isolation of antigens of liver cell fragments associated with rejection of transferred allogeneic lymph-node cells. This method was therefore chosen for the extraction of the water-soluble components of human red cell membranes in this laboratory.

Out-dated blood of the major blood types which was collected in ACD-solution served as the starting material for the preparation of stroma by the method, slightly modified, of Dodge, Mitchell and Hanahan¹³. Stroma routinely so prepared contained less than 3 per cent haemoglobin. The leucocyte count in a typical preparation before haemolysis was less than 10 per cent of the original count. All preparations were screened also for bacterial contamination and spot tests were made with phase-contrast microscopy and electron microscopy to assess the integrity of the ghosts. Several methods for preparing the water-soluble protein of the ghosts were investigated. Removal of the lipid with *n*-butanol at -2° C was the procedure of choice because of its mildness. The effect of reductive cleavage in the absence or presence of urea^{14,15} on the recovery and solubility of the water-soluble material after butanol extraction was explored. The results are reported in Table 1. A typical recovery after butanol extraction of the treated and untreated stroma ranged from 70 to 80 per cent. The highest yield of the water-soluble material was obtained after reduction and alkylation in the absence of urea (16-18 per cent). Ether extracted stroma (Soxhlet) yielded a similar amount of water-soluble material after subsequent butanol extraction. A high degree of solubilization of the intact stroma was obtained in *tris*-mercaptoethanol mixture (0.55 M *tris*/HCl buffer, pH 8.2, containing 0.2 M mercaptoethanol) as used for the reductive cleavage. Irrespective of the method of preparation the water-phase material retained a high degree of solubility in aqueous solvents after lyophilization; low-speed centrifugation, however, was required to obtain a clear solution.

Purification of the water-phase material was attempted by gel-filtration on 'Sephadex G-200' using distilled water or saline as eluents. Two major peaks were separated (Fig. 1) with the water-phase of stroma which was reduced and alkylated in the absence or presence of urea prior to butanol extraction and of butanol-extracted stroma.

Table 1. THE YIELD OF WATER-SOLUBLE MATERIAL AFTER BUTANOL EXTRACTION
(Expressed in per cent of starting material)

	Stroma (untreated)	Stroma (reduced and alkylated)	Stroma (reduced and alkylated in 8 M urea)
Water-phase	11.0	16.3	10.8
Butanol-phase	30.6	35.0	33.8
Interface material	28.5	25.0	32.4

Ultra-violet absorption spectra of the peaks were compared with the starting material and revealed marked differences as shown in Fig. 2. Similar ultra-violet absorption spectra were found also with the water-phases of stroma which had been reduced and alkylated in the absence or presence of urea. The maximum of the first peak was that of a protein (276 mμ); the maximum of the second peak suggested the presence of lipid. This possibility was supported by the determination of the nitrogen content, where peak A contained 7.8 per cent and peak B 0.3 per cent nitrogen, respectively. Haemoglobin content was also determined in the three phases. On the dry-weight basis the water-phase usually contained between 1 and 3 per cent, the butanol-phase less than 2 per cent, and the interface approximately 3 per cent, haemoglobin which was detected as a haemochromogen-pyridine complex¹⁶. Small amounts of this complex were also found in the water-phase after gel-filtration. The biological activity of the water-phase preparations was now tested with the aid of the haemagglutination inhibition method using the Takatsi-micro-haemagglutination plates. The results of stroma and its phases of blood group A are presented in Table 2. It is

evident that the Rh₀(D) antigen is destroyed by reductive cleavage as well as by butanol extraction alone. Both complete and incomplete antibodies were used for testing. Moreover, Rh₀(D), M and N antigens were not detected in the interface layer material or in the butanol-phase. The A-antigen was found in the interface, in the water-phase and also in both peaks obtained by gel filtration as well as in the butanol-phase. Irrespective of the pre-treatment of the stroma, the M and N activity was found in the water-phase and in the peak A of this material after gel filtration.

The presence of M and N antigens in the water-phase and their absence in the interface indicated a separation of water-soluble surface antigens. The water-phase was therefore analysed for its carbohydrate content. Three stroma preparations were compared and the results are tabulated in Table 3. It is evident that butanol extraction is able to release a water-soluble material which contains more than 90 per cent of the sialic acid of the stroma used. The interface contained a small amount of sialic acid as well as hexose and hexosamine as seen in Table 3, and is thus believed to contain a considerable amount of glycoprotein. It is to be noted that the content of sialic acid in the water-phase varied from preparation to preparation and it was considerably lower when determined in the water-phase of stroma which were reduced and alkylated prior to butanol extraction. Work is being carried out to explain the cause of these discrepancies.

The results suggested that water-phase material may be complex in nature, and were therefore investigated further with the aid of electrophoresis in starch gel containing urea and/or mercaptoethanol. Material from group A stroma obtained in the three phases as well as on the first peak was therefore subjected to starch-gel electrophoresis in buffers containing 8 M urea and 0.07 M mercaptoethanol. Two acidic buffers (sodium formate and aluminium lactate) were used. The patterns are shown in Fig. 3. A number of well-defined zones could be separated when untreated lyophilized stroma was dissolved in the reducing solution and applied to the gel (Fig. 3A). No differences were found among the major blood groups, regardless of whether the sodium formate or the aluminium lactate buffers were used for the electrophoretic experiment (cf. ref. 18).

Table 3. CARBOHYDRATE- AND NITROGEN-ANALYSIS OF DIFFERENT STROMA PREPARATIONS, A, B, C, BEFORE AND AFTER EXTRACTION WITH *n*-BUTANOL (Expressed as weight per cent)

	% Sialic acid (21)	% Hexose (22)	% Hexosamine (23)	% Total nitrogen
Stroma	1.2	8.7	1.3	6.5

Comparison of patterns obtained with lyophilized stroma and with interface prepared by butanol extraction did not reveal any significant differences (Fig. 3A and B). Patterns of Soxhlet-extracted and untreated stroma were similar in the distribution of the separated components (Fig. 3A and F). The pattern obtained with water-phase material was less complex and most of the (Fig. 3C) zones present could be identified with those given by stroma. The constant feature of such a pattern was the presence of a component migrating to the anode. This zone is poorly represented in Fig. 3C due to the uneven thickness of the gel, but is clearly evident in the subsequent patterns (Fig. 3D and E). The pattern obtained with material in peak A differed only slightly from that of the water-phase; the mobility of the anodically migrating component was increased (Fig. 3D). Reduction and alkylation of the water-phase material afforded a pattern quite similar to that of unreduced water-phase and peak A material (cf. Fig. 3E). The anodically migrating component was also found. It should be noted that the patterns of these three materials (Fig. 3C, D and E) were further characterized by a 'white' zone which extended from the application point to the slowest of the cathodically migrating zones.

This phenomenon is most pronounced in the reduced and alkylated water-phase. A similar zone was also observed repeatedly with the water-phase material of other blood groups. The studies indicate that a reasonable amount of water-soluble serologically active material can be extracted with *n*-butanol. The yield could be increased by pre-treatment of the stroma by reductive cleavage, and yields up to 20 per cent were obtained depending on the content of haemoglobin in the original material. Inhibition of four haemagglutination doses of anti-A-serum was accomplished with 4-40 µg nitrogen of the water-phase of blood group A. Approximately four times this amount was necessary to inhibit the same dose in the case of blood group A interface material. The latter result may be dependent on the relative insolubility of the interface material rather than a reflexion of low content of A-substance. The loss of the Rh₀(D) activity after reductive cleavage, reported by Green¹⁷, is corroborated in this work. Furthermore the Rh₀(D) activity is also destroyed by butanol- or Soxhlet-extraction. This is an indication that a lipid as well as a protein component is probably implicated in its structural integrity. The serological activity of the M and N substances present in the water-phase was not destroyed by the chemical treatment used. It is to be noted that no M and N activity was found in the interface. This finding is supported by the low sialic acid content of the material. Since about 75 per cent of the recovered nitrogen was present in the interface, the material was re-extracted

Fig. 3. Starch-gel electrophoretic patterns of A, stroma; B, interface; C, water-phase; D, peak A (cf. Fig. 1); E, water-phase (reduced and alkylated in absence of urea); F, ether extracted stroma (Soxhlet). Gel prepared in aluminium lactate buffer (0.015 M; pH 3.2) containing 8 M urea and 0.07 M mercaptoethanol.

with butanol in order to increase the yield of the water-phase. More than 50 per cent of the water-soluble material was obtained after this first extraction and the yield does not increase after the fourth extraction. The electrophoretic pattern, however, is improved after repeated extraction.

The application of urea starch-gel electrophoresis to the investigation of the red cell membranes^{9,18} offers new insight to the complexity of the constituents of such membranes. In spite of the fact that none of the zones except haemoglobin can be linked with definite functions as yet, the means are now available for monitoring further subfractionation of the water-soluble material. The number of separable zones may vary, depending on the age of cells, mode of preparation and electrophoretic conditions. Comparative investigations will now be feasible with mucoids and other membrane constituents obtained by the method described or by other methods. On the basis of electrophoretic results some purification of the water-phase was achieved by gel-filtration (cf. Table I). Peak A contained A, M and N substances. These materials are included in small amounts in the gel. Hence their molecular weight cannot be accurately estimated. However, their molecular weights must be higher than those obtained by Kathan and Winzler¹⁹. Despite the fact that this finding controverts the results obtained by these authors, the type of cells used and methods of their preparation may play a part in the final chemical state of such substances. Our results are, however, in agreement with those obtained by Lisowska²⁰ with respect to the ultra-violet absorption spectra and the molecular weight. The heterogeneity of each of the phases as demonstrated by starch-gel electrophoresis indicates a need for isolation and characterization of each of the components. Only

then can a more rational concept about the assembly of these sub-units in the red cell membrane and their specific biological role be obtained.

PECTIC POLYSACCHARIDES IN THE GROWTH OF PLANT CELLS: MOLECULAR STRUCTURAL FACTORS AND THEIR ROLE IN THE GERMINATION OF WHITE MUSTARD

By SHEILA E. B. GOULD, DR. D. A. REES, N. G. RICHARDSON and I. W. STEELE

Chemistry Department, University of Edinburgh

THE part that the plant cell wall plays in growth has been discussed very thoroughly by plant biologists in recent years¹. Much of the speculation and experiment has stemmed from the hope that wall extensibility, which must play a major part in cell growth and which may have a controlling influence on it, might be adjusted through one set of molecular interactions. 'Cross-linkages' between pectic components of the wall have often been suggested to have this kind of key role; a discussion of the molecular interactions which could exist between pectic polysaccharides in the cell wall is therefore given here from a chemical point of view together with a preliminary account of a chemical approach to the investigation of these interactions in one system.

The possible nature of the association between pectic molecules in the cell wall is suggested by the gels that these substances form *in vitro*. Such gels contain a network of macromolecules that is cross-linked at various points; the number of cross-linkages need only be small, provided they are strong enough to withstand disruptive forces such as osmosis and coulombic repulsion. The presence of repulsive forces is necessary if the gel is to exist in a swollen state. When the galacturonic acid units are methyl-esterified, gels can be formed in the presence of a high concentration of a low-molecular-weight solute such as sucrose, glycerol or ammonium sulphate². Minor changes in molecular structure can prevent gelation^{3,4}, suggesting that the cross-linkages are secondary valence forces between parallel polysaccharide chains that contain

large numbers of consecutive methyl galacturonate units in close contact. The strength of the association in this type of gel is probably, therefore, affected by the distribution of the methyl galacturonate units available for bonding (that is, not carrying any other substituent). Gel formation can occur whether or not esterification is complete⁵, but a proportion of any non-esterified units must occur largely in the undissociated state, or in association with divalent cations (see following). The gel must be stabilized by the presence of solutes which presumably act, in large part at least, by diminishing the osmotic pressure which would otherwise be disruptive.

A different type of gel formation occurs *in vitro* in the presence of divalent cations such as calcium when the polysaccharide is de-esterified to a sufficient degree. Although charge neutralization might be one factor in the mechanism, it seems likely that other effects such as hydrogen bonding between chains and/or co-ordination of the cation by hydroxyl groups are also involved. Otherwise it would be difficult to understand why partial acetylation should affect gel formation^{6,7}, why cation binding should be influenced by the stereochemistry of the uronic acid units⁸, and why acidic polysaccharides such as polysaccharide sulphates should not form gels with divalent cations. The strength of the association in this type of gel is dependent on the intermolecular, and possible intramolecular, distribution of ionized uronic acid units⁹.

Neutral sugars occur in two types of covalent combination in galacturonans. Units of rhamnose, and possibly of other sugars, occur (normally in small amounts) as interruptions in the galacturonan chain; without a more detailed understanding of the stereochemistry of the secondary bonding involved in cross-linking, their effect on gel properties cannot be predicted. The second type is in side-chains which are sometimes very large; it appears that they can often be isolated by degradation of the galacturonan chain with alkali¹⁰. These side-chains would be expected to prevent the alignment of galacturonan chains, and polysaccharides with numerous such side-chains might lose the capacity to form a stable gel structure in the cell wall¹¹, or to do so by different mechanisms. A number of plant slimes appear to be examples of this type. These are laid down in cell walls, often associated with cellulose microfibrils¹². In water they swell to such an extent that the cell is burst; but this effect is not observed if the water contains solute to diminish the osmotic pressure sufficiently. The swelling might be due to an inability to form a compact gel structure, owing to the lack of strong inter-chain binding between the molecules. The slimes seem often to contain a high proportion of neutral sugar units in the main 'galacturonan' chain, numerous short side-chains also being present (for example, cross seed¹³ and linseed¹⁴ mucilages). A similar effect of increased branching in preventing alignment and aggregation of polysaccharide chains has been noted with certain arabinoxylans¹⁵. In the 'normal' pectic polysaccharides that have so far been thoroughly studied^{10,16,17}, relatively few side-chains occur (although this proportion seems rarely to be negligible), and the continuity of the galacturonan chain is less interrupted by other sugar units.

This brief discussion of the chemistry of pectic substances indicates the way in which these molecules are likely to be associated in the middle lamella and perhaps also in the cell wall proper, though here especially their association might be modified by the presence of other types of molecule. The fact that naturally occurring pectic substances are often highly esterified¹⁸ suggests that association via methyl-esterified galacturonic acid units might sometimes be important. The polysaccharide molecules might be synthesized and laid down such that there is a higher proportion of intermolecular relative to intramolecular cross-linkages than can be achieved in synthetic gels. The structure might not then need to be stabilized to exist, as it must *in vitro*, by the control of solute concentration, pH and/or cations present. Even should osmotic stabilization be required, it might be provided by other wall components such as different polysaccharides¹⁹. Calcium, and perhaps other cations, probably participate in the natural cross-linking of pectic polysaccharides. This is suggested by the maceration and improved extraction of pectic substances that is brought about by chelating agents and agents that precipitate calcium ions^{20,21} and by the co-occurrence of calcium and pectic substances in the same region^{20,22}. Such 'cation bridges' might add extra stability to a 'methyl ester linked' gel, or function independently. The presence of covalent ester linkages between wall polysaccharides is another possible type of cross-linkage to be borne in mind. There are therefore many types of molecular change which would alter the association between pectic substances *in vivo*, including changes in the molecular distribution of acetyl and methyl ester groups and neutral sugar units. Although the metabolic control of extensibility could conceivably be achieved through only one of these, it is equally likely that the situation is more complicated. The discussion presented here has been simplified by considering only the association between pectic polysaccharides, and no attention has been given to the role of other wall components which might indeed be more important, especially in some species where the concentration of pectic polysaccharides is very low²³.

Against this background, we have undertaken a chemical study of the pectic polysaccharides of white mustard cotyledons, to look for molecular changes which might correlate with biological changes in the cell walls during germination^{24,25}. The pectic extract was readily separated into a neutral araban and a mixture consisting chiefly of acidic polysaccharides²⁴. Several types of structure are consistent with the results of structural studies on the araban, but it is only relevant here to give one of them (Fig. 1). The other possibilities contain the same structural units in the same proportions, but differ in the way in which the units are arranged. After germination, the araban was present in smaller amount and methylation analysis coupled with quantitative gas chromatography showed that the proportion of branched units in the 'main chain' (Fig. 1) has diminished from 56 to 40 per cent.

Fig. 1 Possible structure for mustard araban; note that this is only one of the types of structure consistent with present evidence

The acidic polysaccharide fraction is very complex and contains several components which appear to be related in that they give similar mixtures of sugars on hydrolysis. The main structural features indicated by experiments on the mixture are shown in the form of a composite typical molecule (Fig. 2). The average degree of branching is quite remarkable, and might be related to the observation that the cotyledon cell walls appear to swell markedly at the onset of germination (cf. the discussion of plant slimes here). One of the acidic pectic components showed a specific tendency to aggregate in the presence of low concentrations of calcium ions, with the formation of an insoluble gel. This behaviour was most conveniently examined using the ultracentrifuge. The relative concentration of this aggregating component increased very much during the germination period.

where Z is D-Xylp . . . or highly branched side-chains containing only arabinose units, perhaps resembling the neutral araban shown in Fig. 1

Fig. 2. Structural units present in the mixture of acidic polysaccharides from mustard embryos

The general conclusions to be drawn from these experiments are as follows. During the early stages of germination, the pectic polysaccharides in the cotyledons remain little changed in terms of total amount present, sugar composition on hydrolysis—and even in electrophoretic mobility which implies similarity with respect to such properties as charge density and perhaps degree of esterification. Dramatic changes are only revealed by more detailed examination of the chemistry of the wall components. The araban, a highly soluble polysaccharide which by analogy with other systems would be expected to have little capacity for intermolecular bonding, decreases in amount during germination to about one-third of the original level. At the same time, the degree of branching is diminished and therefore the capacity for cross-linking of the fraction of araban that remains is probably increased. The acidic polysaccharides (very much the major pectic components) change in such a way that they would appear by their aggregation behaviour to have an increased capacity for intermolecular bonding by 'cation bridging' after germination. These various factors would be expected to result in a firmer, less-extensible overall association. A decrease in the deformability of the cell wall would be expected on biological grounds,

because the period in which the alteration in visible form of the call was most rapid was complete at the point at which cotyledons were taken for analysis (after 4 days, germination). In view of this correlation, it seems possible that pectic polysaccharides are involved in the metabolic control of cell enlargement; their role could either be confined to the middle lamella¹, or be more general throughout the whole wall. The detailed chemistry of the process is not yet clear, but the general factors that might apply are outlined in the first part of this article and the evidence suggests that the chemistry is more complicated than has often been imagined in previous discussions. This function of the pectic polysaccharides would not exclude the possibility that enlargement is dependent on other biochemical changes as well.

We thank Mr. J. W. B. Samuel for a preliminary methylation examination of the mixture of acidic polysaccharides from resting cotyledons; Sir Edmund Hirst for advice; Prof. Robert Brown for sectioning experiments and for advice; Dr. G. O. Aspinall for many reference samples and for advice concerning the chemistry of pectic substances; and Prof. K. Wilson, Dr. R. O. Gould and Mr. A. Haug for further advice.

This work was supported by a grant under the Pioneering Research Program of the Institute of Paper Chemistry, Appleton, Wisconsin. We thank Dr. C. T. Greenwood for the use of the ultracentrifuge and boundary electrophoresis apparatus.

QUANTITATIVE GAS CHROMATOGRAPHY OF AMINO-ACIDS AS TRIMETHYLSILYL DERIVATIVES

By PROF. EDGAR D. SMITH and HOWARD SHEPPARD, jun.*
Graduate Institute of Technology, University of Arkansas, Little Rock, Arkansas

BECAUSE of its speed, accuracy and sensitivity, gas chromatography offers substantial advantages over other methods at present in use for the determination of amino-acids. A critical review of the literature on this problem so far is given by Lamkin and Gehrke¹. In this review, however, the pioneering work of Ruhlmann on the synthesis and separation of the trimethylsilyl derivatives²⁻⁵ is given little attention because of the reported instability of these derivatives. Although Ruhlmann himself is credited with having stated that these derivatives were too unstable for satisfactory quantitative analysis⁶, we feel that this statement is entirely too broad and is possibly in error. It is the purpose of this article to present results showing that quantitative analyses of amino-acids are possible with at least three representative protein amino-acids.

(A) *Synthesis of amino-acid derivatives.* Three methods of synthesizing the trimethylsilyl (TMS) derivative of D,L-leucine were briefly explored as follows:

(1) The leucine was mixed with a 50-mole per cent excess of hexamethyldisilazane (HMDS) and refluxed until a clear solution was obtained and the evolution of ammonia practically ceased. The excess HMDS was removed by distillation at atmospheric pressure, the pot residue cooled, and the TMS-leucine distilled at 10-mm mercury pressure.

(2) The leucine was mixed with 100-mole per cent excess HMDS and refluxed as in method 1. The resulting solution was cooled to room temperature, diluted with about an equal volume of dry petroleum ether, and 50 mole per cent of triethylamine added to serve as a hydrochloric-acid scavenger. Finally, 50-mole per cent of trimethylchlorosilane (TMCS) was added dropwise with vigorous agitation, and the mixture stirred continuously for 2 h. This reaction mixture was then filtered under a nitrogen atmosphere to remove triethylamine hydrochloride and

the clear filtrate distilled as in method 1. This method is a slightly modified version of the procedure proposed by Birkofer and Ritter⁷.

(3) The leucine was mixed with a 30-mole per cent excess of trimethylsilyldiethylamine (TMSDEA) and refluxed on a Nester-Faust semi-micro spinning band still until the overhead temperature dropped to 55.5°C, the boiling-point of pure diethylamine. The diethylamine was then removed at a 10 : 1 reflux ratio. The overhead temperature remained practically constant until the theoretical quantity of diethylamine had been removed and then rose rapidly to 126.5°C, the boiling-point of pure TMSDEA. The excess TMSDEA was removed at this temperature, after which the pot was cooled and the crude TMS-leucine distilled at 10-mm mercury pressure as before. This procedure constitutes a minor variation of the procedure described by Ruhlmann⁶. The TMSDEA used in this work was synthesized in about 50 per cent yield by the method described by Hurwitz, Park and Benneville⁸.

All fractionations of the TMS-leucine derivative were carried out on the Nester-Faust still mentioned in method 3. The purified product yield in method 1 was only about 33 per cent of theoretical and was contaminated with a white solid. Our tests indicated that this solid was pure leucine, confirming the observations of Birkofer and Ritter. These workers believed that this product formed in the distillate because of the incomplete conversion of the amine group to the TMS derivative; two moles of the partially silylated amino-acid reacting to yield a fully silylated product plus free amino-acid.

The two-step synthesis procedure (method 2) was designed to eliminate the difficulty mentioned here and did lead to slightly better yields and appreciably lower contamination of the distillates. However, method 3 was clearly superior to method 2 in our hands and gave nearly quantitative yields of pure TMS-leucine. The former

Table 1. PHYSICAL PROPERTIES AND YIELDS OF TRIMETHYLSILYL DERIVATIVES

No.	TMS-Derivative of	Yield % of theory	BP ° C/press (mm)	Relative retention time *
1	D,L-Alanine	61	76/15	1.00
2	Glycine	82	88/15	1.06
3	D,L-Valine	78	104/10	1.72
4	D,L-Leucine	87	108/10	2.07
5	L-Proline	76	87/5.5	2.63
6	D,L-Serine	50	114/4	3.07
7	D,L-Aspartic acid	95	113/4	4.70
8	D,L-Methionine	89	134/5	4.72
9	D,L-Phenylalanine	91	145/5	5.72
10	L-Lysine	81	147/4	6.67

* On 1 meter column of 10 per cent DC 200 on Gas-Chrom Z, programming from 92° to 200° C at 4 degrees/min, flow rate 100 cc/min helium.

method was therefore used in synthesizing the amino-acid derivatives listed in Table 1. It should be noted in this connexion that the yields of derivative shown in this table are the actual yield of purified product obtained. No attempt was made to account for losses due to still hold-up, intermediate cuts, etc. Ruhlmann has indicated yields of 82–97 per cent for all the amino-acids tested, and we feel that his figures are probably more nearly correct than ours.

(B) *Gas chromatographic analysis conditions and procedure.* As noted in Table 1, columns of 'DC 200' fluid (12,500 centistoke viscosity) on 'Gas-Chrom Z' gave good separations of most of the TMS amino-acid derivatives synthesized in this work. A number of other partition liquids were briefly tested and symmetrical peaks were obtained on such standard materials as 'DC 710', 'Apiezon L', 'SE 52' and 'QF-1'. However, none of these partition liquids was any better than 'DC 200' fluid. Attempts to use other standard partition liquids containing active hydrogen atoms, such as polyglycols or polyesters, failed to give recognizable peaks even after repeated injections or after attempts to react these partition liquids with excess TMSDEA before preparing the columns. In view of the distinct possibility that the TMS derivatives might prove to be too unstable or too reactive for gas chromatography anyway, it was decided to carry out a preliminary quantitative evaluation on the 'DC 200' column. It was further decided to carry out these analyses under isothermal conditions to eliminate errors which might occur due to non-reproducible programming of temperature. D,L-Leucine, D,L-serine and D,L-aspartic acid were the amino-acids chosen for this work as being representative of a neutral, hydroxy-, and acidic amino-acid respectively. An Aerograph model A-350-B dual column temperature-programmed gas chromatograph equipped with a dual 4-filament detector cell was used with a Sargent model SR recorder. Helium was used as the carrier gas and 2 metres of standard 0.25-in. diameter copper tubing was used to contain the packing of 10 per cent 'DC 200' fluid (12,500 centistoke viscosity) on 'Gas-Chrom Z'. The carrier gas flow-rate was set at 100 ml./min, and the column temperature at 160° C, in order to obtain a clean separation of the three amino-acids in an over-all analysis time of 8 min. Initially the injector and detector cell blocks were both set at 230° C, but a few preliminary semi-quantitative tests soon showed that better peak shapes and slightly more reproducible responses were obtained with on-column injection. The injector block temperature was therefore reduced to 160° C in subsequent quantitative work. In view of the known sensitivity of the TMS-amino-acid derivatives to traces of moisture, peak responses were also checked semi-quantitatively before and after the installation of a Matronic XF-100 gas chromatography scrubber in the carrier gas line between the helium tank and the gas chromatographic column. This unit is designed to remove traces of moisture, oil and dirt often found in commercial tanks of helium. Comparison of the data with and without the scrubber showed that the sample responses increased by nearly 40 per cent with the scrubber in place. This definitely showed the desirability of scrubbing the helium for this work even though it was not possible to detect any gain in weight in conventional magnesium perchlorate drying

tubes after the passage of 30–40 l. of this gas through them.

Standard samples of the TMS derivatives of leucine, serine, and aspartic acid were prepared by injecting each of the pure derivatives into a dry, tared, and nitrogen-flushed vial through a self-sealing silicone-rubber septum. The vial was re-weighed after each injection, and finally a calculated volume of TMSDEA was injected to bring the final solution to the desired concentration and the vial again weighed. In this way the weight per cent of the final solution could be calculated accurately.

Reproducibility of sample size injection was checked by injecting replicate 2, 4, and 8 µl. samples into a tared vial. The vials were re-weighed after each injection so that both the reproducibility of injection and the average sample weight per injection could be calculated. The assumption was made in subsequent work that these average weights were also injected into the gas chromatograph. Thus, the size of each amino-acid component could be calculated from a knowledge of the weight-per-cent composition of the sample mixture. Calibration curves were then prepared by injecting triplicate samples of 2–8 µl. of several standard mixtures. Under the gas chromatographic conditions specified, the elution times of the three amino-acids chosen for analysis were 2.2, 3.3, and 6.8 min for leucine, serine, and aspartic acid respectively.

Finally, several mixtures of leucine, serine and aspartic acid were weighed out and converted to their trimethylsilyl derivatives by the following procedure: a mixture of 80–300 µmoles of each of the three amino-acids was suspended in 4–5 ml of TMSDEA in a tared distillation flask. The suspension was refluxed on a Nester-Faust micro spinning-band still for 5–10 min, and then the resulting clear solution was slowly distilled so as to collect 2–3 ml. of distillate over a period of 50 min. Initially the overhead distillate temperature was 55°–60° C, but it gradually climbed to about 120° C at the end of the distillation time. The pot contents were removed from the still and the flask re-weighed so that the amino-acid content could be calculated. An aliquot of this solution was injected into the gas chromatograph and analysed under the conditions previously described.

The statistical correlations observed between the sample size of pure TMS-derivative injected and the average peak areas or peak heights are summarized in Table 2. Attempts were made to improve the precision of the peak area measurements by doubling the recorder chart speed, but no significant improvement was observed. It was concluded that the major cause of the relatively poor precision (95 per cent confidence limits were about ± 10 per cent of the actual amount present) was due to the non-reproducibility of sample injection. This conclusion was confirmed by the following facts: (1) in every case where an unusually high or low response was obtained for leucine, correspondingly high or low responses were also obtained for serine and aspartic acid; (2) when analyses were calculated on a relative, rather than on an absolute, basis, the precision of the analyses was markedly improved (95 per cent confidence limits were ± 0.6 per cent of the actual amount present).

Table 3 summarizes the results obtained on analysing four synthetic mixtures of pure leucine, serine and aspartic acid. Recorder peak height responses were used in this work since there seemed to be no advantage of the more complicated peak area determinations. Minor variations of the procedure described in the experimental section were used in these runs, and it is felt that the reproducibility shown in this table could be improved by strict adherence

Table 2. STATISTICAL CORRELATION OF SAMPLE SIZE AND RECORDER RESPONSE FOR PURE TMS DERIVATIVES*

Amino-acid	Peak heights		Peak areas	
	Corr. coeff.	S.D.	Corr. coeff.	S.D.
Leucine	0.995	0.019	0.995	0.019
Serine	0.995	0.019	0.996	0.018
Aspartic acid	0.995	0.022	0.996	0.019

* Range of sample size, was 0.10–0.70 µmoles for each amino-acid.

Table 3. ANALYSIS OF SYNTHETIC AMINO-ACID MIXTURES

Sample No.	Component	Absolute amount in μ moles			Relative amount (%)		
		Present	Found	% Dev.	Present	Found	% Dev.
1	Leucine	101	81.4	-19.4	33.6	34.4	+2.4
	Serine	100	78.6	-21.4	33.2	30.2	-9.0
	Aspartic acid	100	76.5	-23.5	33.2	32.4	-2.4
2	Leucine	100	67.2	-32.8	32.8	31.9	-2.7
	Serine	80	54.1	-32.4	26.2	26.5	+1.1
	Aspartic acid	125	84.4	-32.5	41.0	41.7	+1.7
3	Leucine	91.1	66.7	-26.8	28.8	29.1	+1.0
	Serine	93.9	68.0	-29.7	29.7	29.4	-1.0
	Aspartic acid	131	92.2	-29.6	41.5	41.5	0.0
4	Leucine	138	114	-17.4	23.2	24.3	+4.7
	Serine	162	131	-19.1	27.2	27.9	+2.6
	Aspartic acid	296	225	-24.0	49.6	47.7	-3.8

to a single procedure. Nevertheless, the data in Table 3 are useful to demonstrate two points: (1) the average yield of amino-acid derivative via the procedure used was roughly 75 per cent for each of the three amino-acids; (2) the relative percentage composition of the mixtures could be calculated with an average precision of ± 3 per cent (95 per cent confidence limit). The latter fact appears

to substantiate the conclusion that all three amino-acids were being converted equally to trimethylsilyl derivative.

In summary, we feel that this work strongly indicates that the trimethylsilyl derivatives may yet prove to be the simplest and best derivatives for the gas chromatographic analysis of amino-acids. Work is continuing to extend this method to additional protein amino-acids and to refine the analytical procedures outlined in this article.

This work was supported by U.S. Public Health Service research grant GM 09776 from the National Institutes of Health.

CORRELATED ATOMIC COLLISIONS IN IRRADIATED CRYSTAL LATTICES

By DR. LEWIS T. CHADDERTON and IAN McC. TORRENS

Physics and Chemistry of Solids, Cavendish Laboratory, University of Cambridge

WHEN crystalline matter is bombarded with energetic radiation—protons, neutrons, α -particles, electrons, fission particles, etc.—the atoms of the lattice are disturbed and some are displaced, either singly or collectively, to form defects. The detailed examination of these processes is the physics of radiation damage, in which interest has been stimulated by the onset of the nuclear age, and with the realization of the importance of crystal defects in many solid-state devices^{1,2}. Only comparatively recently, however, has close attention been paid to the fact that the atoms of an irradiated crystal are arranged in an ordered way on a three-dimensional lattice, though as long ago as 1957 Silsbee predicted that this would be of profound importance³.

The way in which the regularity of the crystal can modify the problem is perhaps best seen in a qualitative way by considering a primary radiation damage event; that is, a collision between an incoming particle and a lattice atom. If the collision is a close one, then sufficient energy is communicated to the struck atom to displace it and, indeed, a cascade or shower of subsequent displacements may ensue. If the energy of the 'primary knock-on', however, is not so great, then the surrounding lattice is able to impose rigid conditions on the possible modes of momentum transfer. Thus, when the struck atom cannot penetrate the surrounding lattice it can only transfer energy and momentum to one of its immediate neighbours, and so the possibility of collision correlation becomes apparent. More particularly, where close-packed rows of atoms exist in the crystal, one may expect an energy pulse, or a sequence of collisions, to be propagated along them. This is the phenomenon of focusing, first suggested by Silsbee³ and discovered in practice more recently through a series of elegant experiments performed by M. W. Thompson *et al.* at Harwell⁴⁻⁶. The bundle of energy which passes down a row of atoms is called a 'focuson', and it is said to have propagated by means of a 'focused collision sequence'. If the close-packed row of atoms is bordered by nearby atoms, then these also may exert some influence on the behaviour of the focuson, and an 'assisted focusing' process, which is very similar to the action which a simple thin converging lens exerts on a beam of light, may occur. When the nearby atoms lie close to the 'optic' axis, then the atomic lens is strong, focusing is enhanced, and the effective focal length is small. Moreover, if the focused collision sequence

is sufficiently energetic, then it can be accompanied by a series of sequential atomic replacements. This is called a dynamic crowdion. Afterwards, of course, owing to the dissipation of energy to the atoms comprising the atomic lenses and because of thermal vibrations of all the atoms, a dynamic crowdion is degraded into a focuson, an interstitial atom is deposited, and the focuson fades away⁷.

One other very important process derives from the existence of close-packed chains of atoms in the crystal, or rather from the open layers, or channels between them. If a primary knock-on enters and moves down such a channel, its interaction with the lattice will be small. It will travel long distances in an almost force-free space and will be constrained to stay there by an effectively infinite potential well created by the atoms in the close-packed chains. By analogy with the focuson, where the particular nature of the process was also emphasized through a high degree of energy localization, a primary of this kind has been called a 'channelon'⁷. The channelon, like the dynamic crowdion, but unlike the focuson, always transfers energy and mass.

The one single factor which perhaps best serves to distinguish between the phenomena of focusing and channelling is the energy at which they occur. Thus, while focusing is essentially a low-energy process (of the order of a few hundred electron volts in the close-packed metals), channelling is generally more favoured at higher energies (of the order of several keV); without any essential upper energy limit.

Computer methods. Both focusing and channelling are amenable to some kind of analytical treatment⁷, but a comprehensive and accurate analysis is ruled out by the difficulties encountered in allowing for many simultaneous atomic interactions—the very core of the correlation problem. Moreover, our knowledge about the interaction potential itself is not very satisfactory, so that in many circumstances a numerical approach can be of greater value at this time. For this reason, Vineyard *et al.* at the Brookhaven National Laboratory have initiated computer calculations of radiation damage in face-centred cubic metals⁸⁻¹¹, and the work has since been extended by Erginsoy and others to the body-centred cubic structure¹². The computer is asked to consider a crystallite containing a reasonably large number of atoms which interact with realistic forces. Atoms on the surface of the crystallite are supplied with extra forces simulating the reaction of

atoms outside, as though the crystallite were embedded in an infinite crystalline matrix, and a radiation damage event starts with all atoms on their lattice sites and all but one at rest. That one atom is initially endowed with arbitrary kinetic energy and direction of motion, as though it has just been struck by an incoming particle. The computer then integrates the classical equations of motion for the set of atoms, showing how the knock-on transfers energy to neighbouring atoms, how the dynamic stages evolve, and how the kinetic energy finally dies away and the atoms of the set come to rest in a damaged configuration.

Our own interest is the particular problem of fission fragment damage in crystals and in determining the part which focusing and channelling are likely to play in the different crystal types. For this reason a computer programme has been established which is similar in general form to that of Vineyard *et al.* but which differs in detail. In particular, a section is taken across the crystallite by the computer and the projected orbits of atoms originally at rest on lattice sites in that plane are automatically plotted. The programme is so constructed that it is a relatively simple matter to change the section taken, the nature of the material—element or compound, and the nature of the binding. The energy of the primary event is very easily controlled. The computation begins with the struck atom directed along a major crystallographic direction and the orbits of all the disturbed atoms in the plane selected, including the struck atom, are plotted out. After a sufficient interval of time the computation is arrested and the direction of the initial knock-on in the primary plane is slightly changed, so that it now makes a small angle with the original major crystallographic direction. The programme is then reset and restarted and a further set of atomic orbits are plotted out on the same diagram. This procedure is continued, the same increment of angle being added to the previous direction at each resetting, until such time as a full 360° has been covered in the plane or, if the plane contains one or more axes of symmetry, until the diagram contains all the necessary information. A new section through the crystallite—a new crystallographic plane—is then selected, and the entire computation followed through again for the same initial atom, and another diagram obtained. Each of these composite diagrams, which we call 'energy correlation diagrams', contains information about the importance of focusing and channelling following primary radiation damage events in the crystal at that particular energy. The idea is best illustrated by choosing a few examples.

We begin by considering an alkali halide lattice—potassium chloride. This is a face-centred cubic structure with singly charged potassium and chlorine ions (both electronic configurations identical with argon) arranged alternately at the lattice points of a simple cubic lattice. The ions are close-packed with an inter-ionic spacing of 3.14 \AA ; so we would expect focusons to be favoured and channelons to be rare. Fig. 1 shows the 80-eV correlation diagram for a struck potassium ion in the $\{100\}$ plane. All the events depicted were run under identical conditions, and continued for the same length of time ($1.2 \times 10^{-13} \text{ sec}$) so as to allow any focusons created to leave the immediate vicinity of the knock-on. The diagram illustrates very effectively the relative importance of the low-index directions in the focusing of energy away from a primary event. In particular, the predominance of the $[110]$ assisted focusing is extremely marked and much more intense than the $[100]$ focusing. The main $[110]$ lines carry some energy from almost all the events, and a large fraction of the energy from some initial projections close to 45° , whereas in the $[100]$ case, only events where the ion is set moving at under 20° focus energy over more than about three lattice spacings. Study of the diagram reveals that subsidiary $[110]$ focusing in adjacent lines is beginning and, if the events

were permitted to continue into the relaxation period, this would undoubtedly become more obvious. Disturbance of the $[110]$ lens by the traversal of a focuson is clearly illustrated. The size of the disturbed region, moreover, is governed by the energy of the primary knock-on, and in the potassium chloride structure the symmetrical spread of this region is very marked. Activity is concentrated along or near to the principal focusing axes.

Now consider a lattice which is characterized by a measure of covalent binding—lead iodide. This possesses a hexagonal crystal structure of the cadmium hydroxide group ($a_0 = b_0 = 4.54 \text{ \AA}$, $c_0 = 6.86 \text{ \AA}$) and consists of 'sandwiches' of planes parallel to the basal (0001) plane, each sandwich being composed of a plane of lead atoms between two planes of iodine atoms. The atoms are packed somewhat loosely if we compare the lattice with potassium chloride, so that channelling of atoms, rather than focusing, might be expected to be a possibility. Fig. 2 shows the 80-eV correlation diagram for a struck lead atom in the $\{1210\}$ plane. Strongly assisted focusing occurs in one of the events for atoms moving in the $[1011]$ direction, since a lead atom travelling in this direction passes through an assisting lens of two iodine atoms, which aids the focusing. However, the distance it must travel before colliding with its successor in the chain is 10.43 \AA , and consequently it does not require to be more than a few degrees off-axis in order to defocus rapidly, due to over-correction by the iodine/iodine lens. Some subsidiary focusing takes place in the $[0001]$ direction, but this is generally short-lived, due to the asymmetry of the adjacent lines of atoms. The relatively long range of the secondary knock-ons which the diagram reveals, and the lack of regularity in the spreading of the disturbance, are both consequences of the high spacings in the open lead iodide lattice. This contrasts markedly with Fig. 1, though undoubtedly some trajectories would cross in this diagram if the events were run into the relaxation period, where $[110]$ replacements and diffusive ionic motions would occur.

So far we have only referred to examples where the correlated atomic motions lead to the generation of focusons. Now we consider the case of channelling, for which we shall in general require higher energy correlation diagrams, though, of course, we dare not go to such high energies that energy losses to electrons would become important, since the programme does not acknowledge

Fig. 1 80-eV correlation diagram for a struck potassium ion in the $\{100\}$ plane of the potassium chloride structure. The diagram consists of many superimposed atomic trajectories. Both simple and assisted focusing occur strongly in the $[100]$ and $[110]$ directions respectively.

the existence of a fine atomic structure. Here we introduce the concept of a primary energy correlation diagram, in which only the orbits executed by the primary knock-on are plotted out. This is simply a device to remove the background of the many secondary orbits which in this case would only complicate the issue. Fig. 3 is the 80-eV primary correlation diagram for the events shown in Fig. 2. The orbits of the knocked-on lead atom show minor variations with angle but do not vary significantly in length. Fig. 4, on the other hand, which is the 1,000-eV primary correlation diagram for a struck lead atom exhibits primary orbits with a very marked angular variation in length and shape. These indicate that within two angular bands of about 30° channelling occurs in the $\langle 1011 \rangle$ directions. There is a transverse oscillation superimposed on atomic motion along this channel, and this tends either to decrease in amplitude ('active' channelling), or to increase rapidly until the atom is knocked out of the channel. This oscillation of an imperfect channelon about the axis, if extrapolated to three dimensions, becomes a spiralling movement, though it is somewhat irregular since the atomic 'lenses' are rather astigmatic.

Conclusion. The primary energy correlation diagram, which is essentially a polar plot of channelon probability, is of value to those interested in this particular phenomenon. The displacement energy correlation diagram, however, which we have not so far discussed, will be of more general interest. In this, for a knock-on directed at a particular angle, the atomic orbits are plotted out for the lowest energy leading to production of a permanent Frenkel pair. Information about this displacement energy, and about the final positions of the vacancy and interstitial, is stored before the computer is instructed to add another increment of angle. The displacement energy correlation diagram may then consist of a plot of those atomic orbits which lead to displacement, including the positions in the lattice of the vacancies and interstitials produced, and, if necessary, of a true polar plot of the displacement probability.

While the methods which have been described here have been developed with a specific purpose in mind, we believe that the correlation diagram can be of use to workers in the general field of radiation damage. Since

Fig. 2. 80-eV correlation diagram for a struck lead atom in the (1210) plane of the hexagonal lead iodide lattice. Strongly assisted focusing occurs in the 40° event for atoms moving in the [1011] direction, but this requires projection within a small angle of this direction, otherwise defocusing takes place immediately. The relatively long range of the secondary knock-ons is a consequence of the very open lattice of lead iodide.

Fig. 3. 80-eV primary correlation diagram for the events shown in Fig. 2. Only the orbits executed by the primary knock-on are plotted out, and though these show minor variations with angle they do not vary significantly in length.

Fig. 4. 1,000-eV primary correlation diagram for a struck lead atom in the (1210) plane of the lead iodide lattice. Orbits with a very marked angular variation in length and shape indicate that within two angular bands of about 30° channelling occurs in the $\langle 1011 \rangle$ directions.

the computer programme can be easily adapted to different structures, a first step might be to catalogue the non-displacement correlation diagrams for the principal planes in the elemental crystal lattices—cubic, tetragonal, hexagonal, monoclinic, etc. This would make available a neat, but qualitative, summary of the relative probabilities of focuson propagation along the major directions in crystals of the elements. A second step would be to see how these diagrams vary with the nature of the interatomic binding—metallic, ionic, covalent, etc.—in going from an element to a compound, and with atomic mass. Thirdly, and somewhat more sophisticatedly, it might be informative to introduce defects—dislocations, interstitials, impurities, stacking faults, etc.—of the type to which the particular crystal is susceptible.

We thank Dr. F. P. Bowden for his advice, the Ministry of Education, Northern Ireland, for a research scholarship (I. McC. T.), and the Science Research Council for the award of a research grant.

LETTERS TO THE EDITOR

PHYSICS

A Wave Mechanical Approach to the Plasma Interaction Problems

WHEN an object moves rapidly in an ionized gas, its surface, if electrically conducting, will become charged due to the differential in mobilities of the electrons and ions in the gas. Assuming that the medium is in thermodynamic equilibrium and consists of singly charged particles only, the surface will acquire a negative potential. The equilibrium surface potential will be reached when the incident fluxes of electrons and ions become equalized by the biased surface potential. A charged body influences, by electrostatic interaction, the trajectories and concentrations of the neighbouring charged particles which, in turn, modify the potential field by their presence as space charges. This electrodynamic phenomenon, which occurs in the immediate vicinity of a body moving rapidly in a rarefied ionized medium, is the plasma interaction of interest. A variety of scientific experiments have led to the discussion of this problem. As an example we may cite the measurement of the upper ionosphere by the use of a satellite probing scheme. The ionospheric quantities of interest, for example, electron density and temperature, must be inferred from the planned measurements made at the satellite body which is, of course, shielded by a cloud of charged particles and their associated potential field. The theory of measurement, therefore, must be based on an understanding of the specific plasma interaction developed.

The conventional approach to the problem consists of treating the Poisson equation which governs the potential field jointly with the Boltzmann equations which determine the concentrations of the charged particles in question. These equations are coupled by the space-charge terms of the Poisson equation and the external-force term of the Boltzmann equation. It would be out of place to review the extensive publications on the subject. Interested readers are referred to the recent review by Al'pert *et al.*¹. Generally speaking, the method of iterative approximations is used starting with a quasineutral particle solution for the particle concentration. Some pertinent references which are exceptions to the iterative approach are discussed later.

I shall present here an alternative approach to the plasma interaction problem which leads to a more rigorous treatment of the charge-field coupling effect, thus shedding more light on the physical process of interaction. In this approach, the motion of the particles is represented by the Schrödinger wave equation instead of the Boltzmann equation as used in the conventional approach. In the present communication, we are interested in the stationary state of the interaction, thus eliminating the considerations of hydrodynamic stability and wave excitations. The absence of magnetic field is also assumed although the formulation can be generalized to include the effect of magnetic field. This omission is justifiable if we are interested in the particle distributions in the zone close to a body moving in a weak magnetic field.

Consider a rarefied plasma flowing toward a fixed (conducting) body at hypersonic speed such that the free stream velocity V_0 is much larger than the thermal velocity of the ions and much smaller than that of the electrons. It is assumed that the characteristic dimension of the body is small compared with the minimum mean free path of the charged particles. Thus the particle flow in

this zone close to the body can be treated as collisionless. To make our problem definite we postulate that the surface of the body absorbs and neutralizes the encountering electrons and ions respectively. This is a reasonable assumption for particles impinging with energy of the order of a few electron volts. It is further assumed that the body is electrically charged to a high negative potential, hence the electron density (n_e) can be approximated by the Maxwell-Boltzmann distribution:

$$n_e(\mathbf{r}) = n_0 \exp[e\varphi(\mathbf{r})/k T_e]$$

where e , k , T_e , φ and n_0 denote the electron charge, Boltzmann constant, electron temperature, electrical potential and electron density at infinity where $\varphi = 0$, respectively.

The Schrödinger wave equation for an ionic particle (m) in steady motion is:

$$h^2 \nabla^2 \psi(\mathbf{r}) + 8\pi^2 m [E - e\varphi(\mathbf{r})] \psi(\mathbf{r}) = 0 \quad (1)$$

where h denotes Planck's constant; φ , potential; E , total energy of the particle in question. The wave function $\psi(\cdot)$ has meaning² such that $|\psi|^2 d\mathbf{r}$ is the probability of finding a particle in volume element $d\mathbf{r}$ at \mathbf{r} . Thus if there are n non-interacting identical particles per unit volume, $n|\psi|^2$ represents the probable number density at \mathbf{r} . It can be shown that for the ionic particles of interest in the plasma interaction problem here concerned, the de Broglie wave-length is negligibly small compared with the Debye shielding distances¹ in which φ varies significantly. We may therefore simplify the solution of equation (1) by using a short-wave-length approximation. In so doing all the 'diffraction' effect (a term borrowed from optics), which is important for the shadow (wake) zone of the flow field, vanishes in this limit, as might be expected. In other words, in the present level of approximation, we limit our discussion to the flow field in the frontal zone facing the stream. It is noted from geometric optics that if the coefficient of the ψ -term were a constant, say α , $\exp[i\alpha(\vec{\beta} \cdot \mathbf{r})]$ would be a solution to equation (1), where $\vec{\beta}$ is a unit vector in the direction of propagation. This result, together with the Wentzel-Kramers-Brillouin-Jeffreys approximation to equation (1) in the one-dimensional case, suggests the following form for ψ (if several rays pass through a point, we may write instead of (2):

$$\psi = \Sigma A \exp[iW(\mathbf{r})],$$

the sum includes one term for each ray through the point):

$$\psi = A \exp[iW(\mathbf{r})] \quad (2)$$

Equation (1), after the substitution of (2), becomes:

$$h^2[(\nabla W)^2 - \vec{\nabla}^2 W] = 8\pi^2 m(E - e\varphi)$$

which reduces by short-wave-length approximation to

$$h^2(\nabla W)^2 = 8\pi^2 m(E - e\varphi) \quad (3)$$

The first-order partial differential equation (3) for W is equivalent to a system of ordinary differential equations for the rays (or trajectories) of the particles. It is a form of Hamilton-Jacobi equation in classical mechanics, as might be expected²; W is proportional to the action function. The possible trajectories of ions are orthogonal to the surfaces of constant W and hence to the surfaces of constant phase of the wave function ψ . The formal solution for ψ can be written:

$$W(\mathbf{r}) = \int 2\pi \sqrt{2mh^{-1} \{E - e\varphi(\mathbf{r}(s))\}} ds \quad (4)$$

where s is a parameter in terms of which the trajectories of ions are described.

The advantage of the present method results from the fact that the Schrödinger equation for ψ is linear for a given φ . It is admitted that the Hamilton-Jacobi equation can be exactly and generally integrated only in a few simple cases. On the other hand, particular solutions with correct initial conditions can often be fairly easily obtained by numerical or graphical methods. In the following we shall illustrate the use of the present method in a plasma interaction problem for which an exact solution for the potential field can be obtained.

Consider a rarefied hypersonic plasma stream with properties as already described impinging on a large conducting plate at a small angle θ to its normal, the x -axis. It is assumed that the plate, which absorbs and neutralizes the electrons and ions respectively, is large, hence the edge effect is negligible and the potential field can be treated one-dimensionally, $\varphi = \varphi(x)$. We have now the Schrödinger equation for the motion of the ions:

$$\frac{\partial^2 \psi}{\partial x^2} + \frac{\partial^2 \psi}{\partial y^2} + \frac{8\pi^2 m}{h^2} [E - e\varphi(x)] \psi = 0 \quad (5)$$

and the Poisson equation governing the variation of φ :

$$\frac{d^2 \varphi}{dx^2} = -4\pi en_0 [\psi^2 - \exp(e\varphi/kT_e)] \quad (6)$$

with the boundary conditions:

$$\varphi = 0, d\varphi/dx = 0, \text{ at } x = -\infty$$

Let $\psi(x, y) = \psi_1(x)\psi_2(y)$ be substituted into equation (5), we obtain the separated equations:

$$\frac{d^2 \psi_1}{dx^2} + \frac{8\pi^2 m}{h^2} [E - e\varphi(x)] \psi_1 = C_1^2 \quad (7a)$$

and

$$\frac{d^2 \psi_2}{dy^2} = C_1^2 \quad (7b)$$

where C_1^2 is the separation constant. Using the short-wave-length approximation (or WKBJ-method) and the upstream condition:

$$\text{at } x = -\infty, \psi \sim \exp[2\pi i(2mE/h^2)^{1/2}(x \cos \theta + y \sin \theta)]$$

and also $|\psi|^2 = 1, \varphi = 0$ we obtain from (7):

$$|\psi|^2 = (1 + e\varphi/E \cos^2 \theta)^{-1} \quad (8)$$

It is interesting to note that the result (8) agrees with that obtained by Hays³, who used the Boltzmann equation method. It is also of interest to compare the present result with that of Ginzburg⁴, who studied a special case ($\theta = 0$) using hydrodynamic equations derived from continuum flows. They check when θ is put equal to zero in (8) and the pressure-term contribution in Ginzburg's result is neglected to comply with the hypersonic assumption.

Equation (6) re-arranged⁵, after $|\psi|^2$ is replaced according to equation (8), and multiplied by $d\varphi/dx$, is integrated to:

$$x - x_0 = \int (8\pi n_0)^{-1} [2E(1 - e\varphi/kT_e)^{1/2} - 2E - kT_e + kT_e \exp(e\varphi/kT_e)]^{-1/2} d\varphi \quad (9)$$

where φ_0 denotes the potential at $x = x_0$; the total ionic energy $E = mV_0^2/2$. In equation (9) we have the structure of the electrical potential shield in front of an inclined plate with negative surface potential φ_0 facing a hypersonic plasma.

The generalization of the present approach to incident ions having a thermal velocity which is small but not negligible compared with V_0 should not prove difficult in view of Bohm and Vigier's interpretation of quantum theory in terms of a fluid with irregular fluctuations⁶.

In rarefied-gas dynamics, an issue of much controversy⁷ exists as to the limit of validity of the hydrodynamic equations. With charged particles the appearance of

collective phenomena which arise because of the long-range electrostatic forces between charges tends to widen the range of validity of the continuum hydrodynamic equations. Still, the discussion has been at the best qualitative. The present formulation helps to shed some light on the transition from micro- to macro-mechanics of plasma flows. Furthermore, the present method appears natural for the treatment of some unsolved problems, such as: (1) unsteady plasma flows; (2) the distribution of ions with bound orbits. In fact it was during an investigation of these problems that I was attracted to the idea of using the Schrödinger equation.

This work has been supported by research grant NsG660 from the National Aeronautics and Space Administration. I thank Ming-Young Yu for his help in the calculations.

Direct Ultramicroscopic Observation of Thermal Scattering in Sodium Chloride

THERMALLY scattered light emitted from nominally very pure single crystals of sodium chloride is directly seen in ultramicroscopic examination of impurity centres^{1,2} using illumination at right angles to the direction of observation (Fig. 1).

This is proved by photographic intensity measurement of the light scattered by a crystal region which is free from individual scatterers. For the reference photograph the intensity of the illuminating light is optically attenuated to 10^{-14} of its original value with a specially designed system using neutral density filters, multiple reflexions and optical sampling.

The relative intensity of the scattered light is determined with an experimental error of ± 15 per cent for the wavelengths of 400 nm and 546 nm of a high-pressure mercury discharge lamp. The results comply with the theoretical values³.

L. Taurel⁴ was able to show this by careful selection of the illuminated portion of the crystal measuring the total intensity of the light emitted by it. With this method one cannot distinguish between the thermal scattering itself and the contributions of individual scattering centres which are due to impurities in the crystal. The measurement presented here overcomes this difficulty.

Fig. 1. Illuminated portion of sodium chloride crystal as observed with an ultramicroscopic arrangement, exposure time 18 h. Only some few scattering centres show up in the right-hand side of the scattering volume.

This work was carried out under the sponsorship of the United Kingdom Atomic Energy Authority. I thank Dr. E. Schneider for his advice.

GEOLOGY

Corona Structures in the Basic Igneous Masses of East Aberdeenshire

THE presence of corona structures in the east Aberdeenshire intrusions is well known. Read¹ described and figured such reaction relations from olivine-gabbros of the Huntly mass. Stewart² noted in the Belhelvie mass common reaction rims surrounding the olivines of the troctolites, the inner being colourless orthopyroxene, the outer amphibole. Sadashivaiah³ described from ultrabasic rocks of the Bourtie area of the Inch mass "Very beautiful double coronas . . . are developed around the olivines at the contacts with feldspar; the narrow inner rim is usually of orthopyroxene and the broader outer rim of fibrous amphibole . . .". Read, Sadashivaiah and Haq⁴ recorded from olivine-gabbros of the Inch mass "intergrowths of various kinds and reaction-associations are beautifully developed. . . . The discontinuous reaction series involved in the reaction association consists of the following members: olivine, hypersthene, augite, hornblende and biotite." In my investigation of the southern end of the Huntly mass I have observed in troctolites double coronas of enstatite and hornblende, and in olivine-gabbros and olivine-norites double coronas of hypersthene and hornblende.

These facts are of considerable importance in the light of recent investigations into the effects of pressure on the melting of enstatite by Boyd, England and Davis⁵. From the results presented, they suggest that "... rocks which show textural evidence of an olivine-liquid reaction relation have developed this relation at relatively shallow depth, probably less than about 9 km".

Stewart² stated that the most reasonable explanation of the form and banded nature of the Belhelvie mass is "that of gravitative differentiation in place, and subsequent tilting to an almost vertical position". Blundell and Read⁶, from palaeomagnetic evidence, state "There is no significant difference between the magnetism of any of the basic masses, and it is therefore suggested that they have remained relatively undisturbed since their formation". Stewart and Johnson⁷ "... feel that the evidence in favour of differentiation in place and subsequent folding, provided by the primary igneous structures, is strong". Read *et al.*⁴ advanced a provisional conclusion for the Inch mass that crystal-fractionation of gabbro magma occurred in place.

From the results obtained by Boyd, England and Davis⁵, it would appear that the basic intrusives of east Aberdeenshire are high-level types, and do not represent a large 'Bushveld type' layered intrusive broken up at depth. The presence of perfect corona and other reaction structures in each of these masses suggests a common factor in their crystallization history; perhaps as one fractionation sequence, for example, Read *et al.*⁴ "... the exposed basic masses of north-east Scottish Province might make one huge sheet"; perhaps as individual bodies of magma crystallizing under similar conditions of depth and

metamorphism. Stewart and Johnson⁷ suggest that the 'older' rocks near the western margin of the Huntly mass south of Knock Hill are in reality 'younger'. If this is correct, and indeed if the Port Soy ultrabasics are also 'younger' and hence correlate with the southern end of the Huntly mass, crystallization of these rocks must have occurred before some, at least, of the regional metamorphism. In contrast, the thermal aureole surrounding part of the Inch mass shows it to be younger than the MacDuff Slates.

In the symposium: "Depth and Tectonics as Factors in Regional Metamorphism", it was suggested by Chinner⁸ that: "On the load pressure assumption, kyanite-sillimanite sequences appear to require not only low geothermal gradients . . . but also depths of burial of the order of 30 kilometres". Any depth burial approaching this figure is at odds with the evidence of the presence of corona and reaction structures in the Aberdeenshire basic masses, which suggest late-tectonic, high-level crystallization.

Variation in regional metamorphism in the country rocks surrounding each of these masses, coupled with investigation of the variation of contact aureoles and the nature of the reaction structures present in each mass, will be necessary before the general history of these masses is elucidated.

Oligocene in California ?

RECENTLY, Eames, Banner, Blow and Clarke¹ stated that strata of Oligocene age are missing in most of America. To support their conclusions, they noted that the Relizian Stage of California was Aquitanian in age and correlated it with the Chickasawhay Formation of the Gulf Coast region. They also noted that the Tumey Formation of California, formerly considered as Oligocene, contains Eocene *Discocyclus clarki*. By ignoring the strata between the Tumey Formation and rocks of the Relizian Stage in the context of a "Brief Review of Significant Faunas from Important Parts of the Central American Region", they created the impression that California also lacks strata of Oligocene age. Indeed, for America they "conclude that in the whole region we have considered (and even as far north as the state of Washington), there are no published records of stratigraphical sections of fossiliferous marine beds which can be dated as Oligocene". Klempell long ago suggested that his 'Miocene' stages below the Relizian were equivalent to the Oligocene of Europe². Later, Klempell and Weaver³ discussed 'Oligocene' molluscs and benthonic foraminifera from part of California, but stated that their local sequence did not necessarily coincide in age with that of the typical European Oligocene.

Planktonic foraminifera, indicative of the Oligocene *Globigerina oligocenic* Zone (= *G. selli* Zone) of Eames *et al.*, have been found in rocks assigned previously to the Zemorrian Stage of the California 'Miocene'. These strata occur immediately below the type section of the overlying Saucian Stage and above the Vaqueros Formation in Los Sauces Creek, Ventura County, California. The benthonic fauna has been documented

previously, but the planktonic foraminifera have been largely ignored⁴.

The planktonic foraminiferal fauna of this section is listed in Table 1 together with the stratigraphic distribution of the species according to Eames *et al.* Although certain of the species of Eames *et al.* are regarded as synonyms of others, I have utilized their names without reviewing the taxonomic complications for lack of space.

Table 1. STRATIGRAPHIC DISTRIBUTION OF PLANKTONIC FORAMINIFERA, ACCORDING TO EAMES *et al.*¹, OCCURRING IN THE *Globigerina oligocaenica* ZONE

Species also occurring in the Zemorrian Stage at Los Sauces Creek are indicated. Zones, characterized by species of *Globigerina*, and their age assignments are from Eames *et al.*¹

Zemorrian Los Sauces Creek	Species	U. Eocene <i>G. turritilina</i> zone	Oligocene <i>G. oligocaenica</i> zone	L. Miocene <i>G. ampliapertura</i> zone

	<i>Globigerina yeguaensis yeguaensis</i>	X	X	
X	<i>Globigerina senilis</i>	X	X	
X	<i>Globigerina ouachitaensis gnaucki</i>	X	X	
X	<i>Globigerina turritilina turritilina</i>	X	X	
	<i>Globigerinita dissimilis</i>	X	X	X
X	<i>Globorotaloides suteri</i>	X	X	X
X	<i>Globorotalia (Turborotalia) permicra</i>	X	X	X
X	<i>Globorotalia (Turborotalia) opima nana</i>	X	X	X
X	<i>Globigerina ampliapertura ampliapertura</i>	X	X	X
X	<i>Globigerina ampliapertura euapertura</i>	X	X	X
X	<i>Globigerina ouachitaensis ouachitaensis</i>	X	X	X
X	<i>Globigerina officinalis</i>	X	X	X
	<i>Globigerina tripartita tripartita</i>	X	X	X
X	<i>Globigerina praebulloides leroys</i>	X	X	X
X	<i>Globigerina praebulloides occlusa</i>	X	X	X
X	<i>Globigerina praebulloides praebulloides</i>	X	X	X
X	<i>Globigerina angustiumbilicata</i>	X	X	X
X	<i>Globigerinita martini scandretti</i>	X	X	
X	<i>Globorotalia (Turborotalia) postcretacea</i>		X	
	<i>Globigerina tripartita lapuriensis</i>		X	
X	<i>Globigerina oligocaenica</i>		X	
X	<i>Cassigerinella chipolensis</i>		X	X
X	<i>Globigerina ouachitaensis ciperoensis</i>		X	X

The *Globigerina oligocaenica* Zone, according to Eames *et al.*, is characterized by the restricted occurrence of *Globigerinita martini scandretti*, *Globorotalia (Turborotalia) postcretacea*, *Globigerina tripartita lapuriensis*, and *G. oligocaenica*; by the last appearances of *Pseudohastigerina micra*, *Globigerinita unicava primitiva*, *G. pera*, *Globorotalia (Turborotalia) increbescens*, *Globigerina yeguaensis yeguaensis*, *G. yeguaensis pseudovenezuelana*, *G. senilis*, *G. ouachitaensis gnaucki* and *G. turritilina turritilina*; and the first appearances of *Cassigerinella chipolensis* and *Globigerina ouachitaensis ciperoensis*. As can be seen in Table 1, the species listed by Eames *et al.* from this zone which were not found at Los Sauces Creek have stratigraphic ranges broader than the *G. oligocaenica* Zone. Of the missing species, only the absence of *Pseudohastigerina micra* is critical as the zone is most clearly defined by the overlapping ranges of this species and *Cassigerinella chipolensis*¹. However, in view of the abundant occurrence in the Los Sauces Creek section of all the species elsewhere restricted to the *G. oligocaenica* Zone, and the overlapping ranges of *Cassigerinella chipolensis* with *Globigerinita unicava primitiva*, *Globorotalia (Turborotalia) increbescens*, *Globigerina ouachitaensis gnaucki*, *G. senilis*, *G. yeguaensis pseudovenezuelana* and *G. turritilina turritilina*, these strata cannot be assigned to any other than Eames *et al.*'s *G. oligocaenica* Zone.

This fauna clearly establishes the presence of Oligocene marine sediments in California, contrary to previous implications and statements. Together with the now established presence of this zone in the Gulf Coast region⁶, these results suggest that widespread uplift, resulting in non-deposition of sediments throughout these parts of

America as suggested by Eames *et al.*¹, did not occur during the Oligocene.

GEOCHEMISTRY

Enrichment of Iron during Accretion in the Solar Nebula

THE anomaly between the abundances of iron in the solar system derived from solar spectra and of that from meteorites is well known¹. Relative to silicon, the abundance of iron in the chondritic meteorites appears to be several times larger than that observed in the Sun. Normalization to any other common element introduces a variation by a factor of two at most. The data are given in Tables 1 and 2. The solar and chondritic abundances of cobalt and nickel show a much smaller and perhaps not significant variation. Pottasch² determined the abundances of several elements in the solar corona, finding an increased abundance of iron relative to silicon, compared with the abundances derived from the photosphere by Aller *et al.*^{3,4}. These workers who have provided the most recent estimates of solar abundances, conclude, after careful examination of the problem, that "there seems no escape from the conclusion that the solar Fe/silicon or Fe/Fe group ratio is smaller than in the meteorites"⁴. Results by Fowler *et al.*^{5,11} on the relative abundances of the iron-group elements predicted from theories of nucleosynthesis, which correctly reproduce isotope ratios, are in substantial agreement with the solar-derived iron abundance. The chondritic iron/silicon and iron/cobalt/nickel ratios are securely based on extensive chemical analyses and are unlikely to be seriously in error.

It is assumed in the following discussion that the solar abundance of iron is close to that of the original solar nebula and that the meteorites have been enriched in iron. It is not proposed to argue the alternative, which seems less likely from consideration of the overall element abundances and the relative amounts of material involved. It is difficult to devise methods of fractionating iron from nickel and cobalt in geochemical processes. For example, reduction processes⁶ will preferentially concentrate nickel in the metallic phase and thus processes involving addition or removal of such a phase will not account for the observed discrepancy in iron/nickel ratios. These chemical difficulties indicate that probably other processes have been effective in causing the enrichment of iron in chondritic meteorites.

Latimer⁷ and Urey⁸ showed that elements in the original solar nebula would be oxidized at the prevailing low

temperatures, and also showed that the common metals could occur as oxides. According to the data of Ringwood⁶, iron would exist as magnetite, and partly in iron silicates, at low temperatures of about 400° K. Magnetite is ferromagnetic and retains this property to low temperatures despite a transition to an orthorhombic form at 133° K.

Recent workers on the early history of the solar system, notably Hoyle *et al.*⁹⁻¹¹, have appealed to a magnetic torque coupling between the early Sun and the disk of dust and gas, to solve the long-standing problem of transfer of angular momentum from the Sun to the planets. In Hoyle's model the transfer of angular momentum causes the material of the disk to move out to the region of the major planets, leaving the region of the terrestrial planets and meteorites free of dust and gas. Condensed bodies larger than a metre or so in diameter are left behind. The material forming the meteorites and terrestrial planets must have condensed prior to the removal of the dust and gas. If accretion takes place during the outward movement of material in a magnetic field as proposed by Hoyle⁹, then ferromagnetic material may preferentially accumulate. If the field is non-uniform, such aggregations may trigger the condensation process for non-magnetic material. It is hoped to investigate several possible models in detail.

Magnetite can thus be selectively enriched. Nickel and cobalt oxides are not ferromagnetic and will condense in proportion to their original abundances, in the solar nebula, with the other non-volatile elements. Probably minor amounts of nickel and cobalt will be incorporated in the magnetite, depending on conditions in the nebula. This could account for the apparently higher chondritic abundances for these elements, if the differences are significant. Magnetite from the Orgueil carbonaceous chondrite is nickel-rich, but the entry of nickel could have occurred during recrystallization. Thus iron can become selectively enriched by this process and afterwards accreted into the parent bodies of the meteorites and, presumably, the terrestrial planets. This process, which is unlikely to be uniform, provides an additional possibility to explain the varying density of the terrestrial planets.

I thank Prof. W. A. Fowler for his advice.

Compared with palladium, the generally much lower solubility of hydrogen in platinum cathodes is reflected by much more rapid changes of E following electrolysis. This, taken together with inexact knowledge of the bulk solubility of hydrogen in platinum as a function of electrode potential near 25° C, and of the diffusion constant governing hydrogen in platinum, makes it more difficult to assess directly the magnitude of overpotential components reflecting the hydrogen content of either the surface or of the bulk of platinum cathodes.

In Fig. 1, values of η , as functions of current density i (m.amp cm⁻²), at platinized platinum cathodes (in the form of 2-cm lengths of wire) are compared with both η and the component η_a recorded at geometrically similar palladized palladium cathodes under similar experimental conditions, in 1.0 N hydrochloric acid, over a low range of current density where η_a can be the major component of η . The catholyte was saturated and stirred by a stream of bubbles of hydrogen. Both η and E were measured with respect to a platinum/hydrogen electrode immersed beside the specimen. Palladium specimens were palladized from a solution of 1 per cent palladium chloride in 0.1 N hydrochloric acid; platinum was platinized from chloroplatinic acid containing 1 per cent platinum chloride and 0.2 per cent lead acetate at current densities from 15 to 150 m.amp cm⁻² for 1 min.

Fig. 1 illustrates that for wires of equivalent diameters there is good agreement between plots of $\log i$ against both η and η_a for palladized palladium and η for platinized platinum. Also illustrated in Fig. 1 are experimental values of η_a compared with plots of $\eta_a = 0.0295 \log (i + i_0)/i_0$, in which i_0 equals $2PFk_0/N$, where P is the pressure under which hydrogen is dissolved, F and N are Faraday's constant and Avogadro's number respectively, and the rate constant k_0 has been calculated from measurements of the open circuit potential E of the palladized palladium electrodes in the hydrogen-saturated catholyte prior to cathodization^{2,3}. The plots in Fig. 1 indicate that, again for wires of the same diameter, experimental values of η for platinized platinum also would show good agreement with the appropriate plot of $\log (i + i_0)/i_0$. This corollary seems sound evidence that, over this relatively low range of current densities, the total overvoltage η at platinized platinum can be comprised primarily—as a limiting case—of the component η_a , which is in turn governed by the transport of hydrogen molecules away from the cathode through the Brunner-

Fig. 1. Plots of η against $\log i$ for platinized platinum cathodes. (*, 0.10 mm; +, 0.25 mm; ×, 0.457 mm diam. wires). Also, η (barred symbols) and η_a plotted against $\log i$; and η_a (filled symbols) against $\log (i + i_0)$ for palladized palladium cathodes (○, 0.122 mm, and ◇, 0.274 mm diam.).

CHEMISTRY

Diffusion or Hydride Component of Hydrogen Overpotential at Platinized Platinum and Palladized Palladium Cathodes

At suitably activated palladium cathodes, the diffusion or hydride component of hydrogen overpotential η_2 (or η_d) can be separated conveniently from the total apparent overpotential, η , by extrapolation of plots against time of changes in the open circuit potential, E , measured after cessation of electrolysis¹⁻³.

Fig. 2. Examples of fluctuations of η with time found with platinized platinum cathodes as recorded during electrolysis with a specimen of 0.25 mm diam. Current density (mA cm⁻²): □, 5.20; ●, 2.27; △, 1.47; ■, 0.93; ○, 0.67.

Nernst boundary layer^{2,3}; this conclusion lends support to a similar interpretation by Kandler, Knorr and Schwitzer⁴ of their results obtained at 'bright' platinum cathodes in 2.0 N sulphuric acid.

The lower value of i_0 obtained with the larger diameter palladium wire, and the consistently higher values of η at a given current density for the platinum wires of larger diameter, are both typical of the findings in repeat experiments. These results seem consistent with the increase in the effective thickness, δ , of the Brunner-Nernst layer with increased wire diameter, reported by Fallon and Castellan⁵.

Electrode-potential measurements were recorded using a 'register printer' (Solartron model ED 1176) printing 12 readings per sec, fed from a digital voltmeter (Solartron model LM 1010); and over these short time-intervals substantial fluctuations of the total overvoltage, η , at platinized platinum cathodes were revealed—as shown, for example, in Fig. 2 (results plotted in Fig. 1 represent mean readings). The rapidity of these fluctuations was very much reduced by interrupting the stirring of the solution, but slow oscillations of η with time still remained. In analogous experiments with palladized palladium these fluctuations of η were not observed (nor have they been observed in preliminary measurements with 'bright' platinum cathodes): it seems possible that they reflect local changes of the hydrogen content of the surface, which, paralleling the low solubility of hydrogen in platinum, may be expected to be relatively sensitive to variations in the rate of desorption of hydrogen molecules away from the surface by a transport mechanism—which, in turn, is governed by the stirring conditions prevalent at all points on the cathode surface.

Electron Spin Resonance Spectrum of Cu⁺⁺ in Diamine Oxidase

THE electron spin resonance spectrum of hog kidney diamine oxidase (DO) has been measured. DO is a cupric enzyme and is similar in properties to histaminase and monoamine oxidase (MO). The electron spin resonance spectrum of the cupric ion in MO was reported by Yamada *et al.*¹. They have shown that copper is the only ion of those tested (Cu⁺⁺, Fe⁺⁺, Fe⁺⁺⁺, Co⁺⁺, Ni⁺⁺, Zn⁺⁺) which

was able to reactivate their MO. The work reported here i additional evidence that copper is associated in some manner with the activity of amine oxidases. This work indicates that Cu⁺⁺ forms either a chelate binding one of the DO prosthetic groups (pyridoxal phosphate or flavin adenine dinucleotide) to the apoenzyme, or else a chelate which holds the DO in a configuration in which it is an active enzyme. Changing or breaking this chelate inactivates the enzyme.

Powdered and liquid (100 mg DO/10 ml. 0.1 M phosphate buffer at pH 7.10) samples of DO were examined using a Varian V-4500 X-band spectrometer with 100 kc/sec magnetic field modulation. Fig. 1 shows spectra for powdered and liquid samples of active DO at room temperature. The lines shown are characteristic of Cu⁺⁺ in tetragonal symmetry. Table 1 gives the experimental values for the g -factors and the hyperfine constants.

The powdered sample showed two other resonances, a very broad (~600 gauss) slightly asymmetric line at $g = 2.05 (\pm 0.05)$, and a symmetric line at $g = 2.02 (\pm 0.02)$ which was 28 gauss wide. These lines did not appear in the liquid sample. My DO was rather impure and, when dissolved in the buffer, a large amount of residue collected in the bottom of the sample. This residue is probably protein impurity and was filtered out of the liquid sample. The fact that these lines did not appear in the filtered liquid sample indicates that they are probably the result of some magnetic ion or ions (probably Fe⁺⁺⁺) associated with the protein impurities. The liquid spectrum resembles very nearly the electron spin resonance spectrum for Cu⁺⁺-histidine complexes reported by Malmström and Vänngård².

When the powdered and liquid samples of DO were heated for 1 min in a temperature bath at 70° C, the cupric spectrum disappeared. At lower temperatures the spectrum faded more slowly as shown in Fig. 2. This is the temperature range in which DO loses its activity. This disappearance could result from two factors: (a) the Cu⁺⁺ could be reduced to Cu⁺; (b) the crystal structure surround-

Fig. 1. Electron spin resonance spectrum of room temperature samples of diamine oxidase: (A) liquid sample; (B) powder sample. The arrow indicates the resonance position of free electrons.

Fig. 2. Electron spin resonance spectrum of powder samples of diamine oxidase heated for various times in a temperature bath at 55°C

ing the Cu^{++} could change in such a fashion as to cause the spectrum to disappear. The latter choice is preferred for reasons given here. Cu^{++} normally co-ordinates strongly with four ligands in a square-planar structure. In such a structure the Cu^{++} valence electrons could form covalent bonds in such a way as to have no unpaired electrons (diamagnetic). If, however, the bonds are more ionic, the Cu^{++} can also co-ordinate less strongly, with two ions perpendicular to the plane, thus forming a distorted octahedral structure with tetragonal symmetry. The Cu^{++} in this case is paramagnetic. Lifschitz *et al.*³ have shown that differences in stability of the two forms are in some cases very slight, since a given complex of chelate may be converted between the diamagnetic form (covalent dsp^2 electron states) and the paramagnetic form by only a slight change in conditions⁴.

Table 1. THE g -FACTORS AND HYPERFINE CONSTANTS FOR Cu^{++} IN DIAMINE OXIDASE AND OTHER Cu^{++} -PROTEIN COMPLEXES
All data except for DO are from Malmström and Vånnård (ref. 2)

Protein	g_{\perp}	g_{\parallel}	$A_{\perp}(\text{cm}^{-1})$	$A_{\parallel}(\text{cm}^{-1})$
Diamine oxidase	2.05	2.25	≤ 0.004	0.021
Histidine	2.083	2.230		0.018
Laccase	2.048	2.197		0.009
Ceruloplasmin	2.056	2.209		0.008

The experimental values of g_{\parallel} , g_{\perp} , and A_{\parallel} given in Table 1 can be used to calculate several parameters which indicate the degree of covalent bonding of Cu^{++} to its neighbours. An investigation by Maki and McGarvey⁵ has shown that a parameter a^2 (related to g_{\parallel}) is reduced in value from a maximum of one as the covalency in the σ - and π -bonds in the plane of the ligands becomes stronger. Another parameter $4/7 a^2 + x$ is reduced by the covalency of in-plane σ -bonding. The results for DO ($a^2 = 0.60$ and $4/7 a^2 + x = 0.83$) indicate that there is some covalent bonding of Cu^{++} to its ligands, especially π -bonding in the plane. Nitrogen is known to form stronger covalent bonds than oxygen, and the value of a^2 for DO conforms to those reported by Malmström and Vånnård² when Cu^{++} is in a plane of four N. This result is certainly not conclusive.

Malmström and Vånnård have found that the hyperfine constant A_{\parallel} in laccase and ceruloplasmin is much smaller than in other protein-copper complexes. In these two enzymes the copper changes valence when the enzyme performs its catalytic action. If the unpaired electron of Cu^{++} in these enzymes were highly delocalized, this would facilitate the valence change and could also reduce the value of A_{\parallel} . However, in DO, A_{\parallel} is very large, indicating that the unpaired electron is not free for valence changes.

In summary, it appears that Cu^{++} is necessary as a chelating agent in active DO. The Cu^{++} in the active enzyme is co-ordinated strongly with four ligands (probably N) in a plane, and loosely with two ligands perpendicular to the plane. When the enzyme is de-activated by heating, the Cu^{++} forms diamagnetic covalent bonds in the plane, and is no longer co-ordinated perpendicular to the plane. The unpaired Cu^{++} electron of the active enzyme is not delocalized

as it is in other enzymes that change valence during their catalytic action (laccase and ceruloplasmin).

Use of Dimethyl Sulphoxide in Liquid Scintillation Counting

DIMETHYL sulphoxide is a polar solvent which is miscible with many organic solvents including toluene. It is an excellent solvent for polysaccharides, proteins and macromolecules generally. Though we expected that it would be a quencher we thought that its solvent properties might make it useful for holding water-soluble substances in solution in liquid scintillators.

Fig. 1. Effect of dimethyl sulphoxide on counting efficiency of toluene phosphor

Dimethyl sulphoxide, far from being a serious quencher, is itself a scintillation solvent, albeit an inefficient one. To obtain the results shown in Fig. 1, phosphors were made by dissolving 40 mg polyphenol oxide and 5 mg 1,4-bis-2-(5-phenyloxazolyl)-benzene in 10 ml. of a varying mixture of toluene and dimethyl sulphoxide. The activity added was in the form of carbon-14-labelled hexadecane and was counted in the Packard 'Tricarb' model 3303. Though there is no obvious explanation of the shape of the early part of the curve it is clear that up to 13 per cent of dimethyl sulphoxide enhanced rather than quenched the scintillations. The results are sufficiently encouraging for us to continue investigations on the use of dimethyl sulphoxide as a solvent for counting tissues.

Rate of Micelle Formation of Sodium Alkyl Sulphates in Water

THE description of the properties of aqueous detergent solutions in terms of a chemical equilibrium between monomers and micelles has proved very fruitful. Thermodynamic as well as transport behaviour has been analysed from this point of view. The detergents most extensively investigated in the past are the sodium alkyl sulphates, and for these a satisfactory explanation may be given of critical micelle concentrations (c.m.c.),

micellar weights, and the influence of temperature, electrolyte concentration and the like, on these quantities.

Less attention has been paid to the kinetics of micelle formation, that is to the question of how long it takes to reach chemical equilibrium in a solution at a given temperature, pressure and total detergent concentration. This question becomes important when the conditions vary with place and/or time, such as during diffusion in a concentration gradient. Another example is the adsorption of a detergent, primarily of monomer molecules, on a freshly-formed oil-water interface as, for example, in suddenly-formed emulsions: micelles have to disintegrate to maintain the equilibrium monomer concentration. Apart from this, micelle formation in itself is an interesting multi-step consecutive chemical reaction.

Some recent papers have been devoted to this subject. From flowing-junction experiments Jaycock and Ottewill¹ concluded that the time of micelle disintegration of sodium dodecyl sulphate and of alkylpyridinium salts was certainly shorter than 10 millisecc. Nagakawa and Inoue² performed nuclear magnetic resonance measurements on a number of ω -phenylalkyltrimethylammonium bromides; the average time a monomer forms part of a micelle was found to be shorter than 10^{-4} sec.

We have made a direct measurement of the relaxation time of micelle formation for sodium dodecyl sulphate (SDS) and sodium tetradecyl sulphate (STDS) in water.

Chemical relaxation was studied with the pressure-jump method as developed by Strehlow and Becker³. This method can be used if a chemical reaction is accompanied by a change in electrical conductivity. This condition is satisfied in the case of SDS and STDS, the equivalent conductivity of the micelles being about one third of that of the monomers; the same property was selected by Jaycock and Ottewill¹ to observe micelle disintegration. An additional (though not necessary) circumstance that favours application of the pressure-jump method is the appreciable influence of pressure on the micellar equilibrium: the partial specific volume of micellar SDS exceeds that of monomeric SDS by about 5 per cent.

The method is based on the principle that the primary effect of a sudden pressure increase, in a solution originally in chemical equilibrium, is an equal relative increase in concentration of all species; the ratio of the concentrations therefore remains the same. Subsequently, in a way determined by the kinetics of the particular chemical reaction, the concentrations will change to their new equilibrium values which correspond to the new pressure and the new total solute concentration (which is higher, owing to the compression). These processes are followed conductometrically. For small deviations from equilibrium the chemical reaction may be described in terms of chemical relaxation times τ_c , of which there are as many as there are independent reaction steps.

Experimentally an instantaneous pressure-jump cannot be brought about. In general an exponential pressure decrease is applied; the relaxation time, τ_p , of this decrease has a lower limit of about 5×10^{-5} sec. In the original apparatus, which was a copy of Strehlow's instrument except for a few details to be described elsewhere, only τ_c -values down to this value could be measured.

Measurements on SDS solutions with this apparatus did not reveal any chemical relaxation; for SDS, therefore, τ_c is certainly smaller than 5×10^{-5} sec.

By introducing a simple but essential change in the way of following the conductivity change, we were able to lower the limit of measurable τ_c -values to about 10^{-6} sec. To explain this, the principle of the measuring device, a Wheatstone bridge, is shown in Fig. 1. Cell *m* contains the solution (in this case SDS in water) to be investigated, cell *b* a solution of a reference electrolyte (KCl) the conductivity of which changes exactly in phase with the pressure.

By means of a simple calibration one finds the relation between V , the measured voltage difference between the

points 1 and 2, and $\Delta R(t)$, the unbalance of the bridge. In the simple case when there is only one chemical relaxation time $\Delta R(t)$ obeys the following equation:

$$\begin{aligned} \Delta R(t) &\equiv R_{m,0} + R_m(t) - R_{b,0} - R_b(t) \\ &= -R_m(t=0) \left[K_1(1 - e^{-t/\tau_p}) - \right. \\ &\quad \left. \left(\Delta \frac{\Delta \kappa}{\kappa} \right) \left(1 - \frac{\tau_c}{\tau_c - \tau_p} e^{-t/\tau_c} + \frac{\tau_p}{\tau_c - \tau_p} e^{-t/\tau_p} \right) \right] \\ &\quad + R_b(t=0) K_2(1 - e^{-t/\tau_p}) \end{aligned} \quad (1)$$

provided the bridge is in balance before the pressure release. The constants K_1 and K_2 are related to equilibrium properties of the systems in cells *m* and *b*, respectively. The quantity $\Delta \frac{\Delta \kappa}{\kappa}$ represents the difference between the relative conductivity changes (for a pressure change equal to the total pressure-jump) of the particular SDS solution above the c.m.c. and that below the c.m.c.; the values of $\Delta \frac{\Delta \kappa}{\kappa}$ can be found from separate experiments.

One sees that in this original arrangement the more τ_c decreases, the more ΔR approaches a simple exponential function of t governed by τ_p .

We then decided to have the bridge in balance not only before releasing the pressure but also at the end of the relaxation processes. Equation (1) shows that the only way to do this is by changing $R_b(t=0)$, that is by varying the KCl-concentration in cell *b* until this requirement is met; K_2 depends on the type of electrolyte in cell *b* but not on its concentration. If conditions for balance before and after the release are satisfied, the expression for $\Delta R(t)$ becomes:

$$\Delta R(t) = R_m(t=0) \left(\Delta \frac{\Delta \kappa}{\kappa} \right) \frac{\tau_c}{\tau_c - \tau_p} [e^{-t/\tau_p} - e^{-t/\tau_c}] \quad (2)$$

and the bridge signal will, temporarily, differ from zero only if there is a chemical relaxation. τ_c is then easily found from the extreme value, $\Delta R_{\text{extr.}}$, of $\Delta R(t)$. From equation (2) one derives:

$$\frac{\Delta R_{\text{extr.}}}{R_m(t=0)} = \left(\Delta \frac{\Delta \kappa}{\kappa} \right) \frac{\tau_c}{\tau_p} \quad (3)$$

Fig. 1 Diagram of experimental arrangement

Fig. 2 Bridge signals for SDS and STDS. Time proceeds from left to right. Pressure release starts at the arrows. Frequency used 30,000 c.p.s. The c.m.c. of SDS is at 0.23 per cent w , that of STDS at 0.06 per cent w . a, SDS, $T = 15^\circ \text{C}$, conc. 0.3 per cent w , b, SDS, $T = 15^\circ \text{C}$, conc. 0.18 per cent w ; c, STDS, $T = 35^\circ \text{C}$, conc. 0.095 per cent w , d, STDS, $T = 35^\circ \text{C}$, conc. 0.048 per cent w .

SDS solutions, investigated in this arrangement, did show chemical relaxation, but only at concentrations exceeding the c.m.c. This indicates that micelle formation is responsible for the relaxation signals, for only above the c.m.c. does $\Delta \frac{\Delta x}{x}$ differ from zero.

Representative oscillograms are shown in Fig. 2. For SDS at $T = 25^\circ \text{C}$ and a concentration of 0.5 per cent w , and for a 50 atmospheres pressure drop, we found:

$$\Delta \frac{\Delta x}{x} = 0.0060; \frac{\Delta R'_{\text{extr.}}}{R_m(t=0)} = 0.0008 \pm 0.0003$$

With $\tau_p = 6.5 \times 10^{-5}$ sec this leads to:

$$\tau_c = (1.3 \pm 0.5) \times 10^{-5} \text{ sec}$$

The τ_c values scarcely depend on the SDS concentration and they decrease only slightly with increasing temperature; we made experiments at 15° , 25° , 35° and 45°C . The average value for all experiments is:

$$\tau_c = (1.2 \pm 0.5) \times 10^{-5} \text{ sec (SDS)}$$

Analogous results were obtained for STDS, which was only investigated at $T = 35^\circ \text{C}$. We found:

$$\tau_c = (2.0 \pm 0.5) \times 10^{-5} \text{ sec (STDS)}$$

A complete account of this work, as well as a discussion of the kinetics of micelle formation, is being prepared. Here we will mention one problem: the signals of the type shown in Fig. 2 were analysed as if they were caused by one relaxing mechanism only. Admittedly, a more detailed analysis, even in terms of as few as two relaxing mechanisms, would have been impossible. Still, our procedure is correct only if from a whole set of relaxation times, numbering $n-1$ in the case of micelles containing n monomers, a single one predominates completely. Calculations on the kinetics which will justify or invalidate our procedure are now being carried out.

Polarization and Hybridization

Two types of polarization that can occur by bond formation are: (i) the result of concentration of charge due to the overlap of atomic orbitals; and (ii) the actual polarization of the basis orbitals. Mulliken¹ has described this second type of polarization and its effect as a function

of the overlap integrals for certain diatomic molecules. In all cases it was observed that the addition of a given amount of a $2p$ Slater type orbital (STO) into a hybrid orbital produced the largest change in the overlap if the hybrid orbital was a $2s$ STO. This observation led to the well-known phrase "A little hybridization goes a long way". The lowering of the energy of the system due to the increase in the overlap integral must be larger than the increase in energy incurred by the inclusion of the higher energy $2p$ STO if the polarization is to be useful. We are inclined to reserve the word 'polarization' for this type of hybridization for the following reasons: (a) the process described displaces the centroid of the electronic charge distribution from the nucleus; (b) this concept can be readily extended to polyatomic molecules and is not dependent on the 'localized bond' approximation (this will prove particularly useful for molecules containing lone-pair electrons); (c) it distinguishes this type of hybridization from the hybrid orbitals obtained from molecular orbitals by a unitary transformation.

It will be useful to have a measure of polarization in the preceding discussion. As an example, let us set up the four molecular orbitals for H_2O (ignoring inner shell orbitals) using a minimal basis set of orbitals consisting of $2s$ and $2p$ STO's on oxygen and $1s$ orbitals (h) on each hydrogen. This is the most general set that is useful to the chemist:

$$\varphi_1 = \lambda_1[(2s) + \alpha(2p_x)] + \mu_1(h_1 + h_2)$$

$$\varphi_2 = \lambda_2[\beta(2s) + (2p_x)] + \mu_2(h_1 + h_2)$$

$$\varphi_3 = \lambda_3(2p_y) + \mu_3(h_1 - h_2) \quad \varphi_4 = (2p_z)$$

where the oxygen nucleus is the origin of the co-ordinate system and the x axis bisects the $\text{H}-\text{O}-\text{H}$ angle. The polarization of the valence shell orbitals on oxygen will be defined as the coefficient of the product $(2s)(2p_x)$ obtained by squaring each orbital φ_i and adding. This is basically a function of α and β . This type of polarization is not possible for atoms in molecules with highly symmetrical environments such as carbon in methane. In methane the hydrogen orbitals can be polarized in this way.

Mulliken's results are all included in this type of polarization as long as there are no lone-pairs in the valence shell. Thus we should distinguish between bond polarization, specifically considered by Mulliken, and shell polarization, as already described. Bond polarization is well defined for a few diatomic molecules because each bond involves just two nuclei, but in general it is not particularly useful since other hybridizations may be involved, the hybrids may not necessarily lie along the internuclear axis of a bond, and more than two nuclei may be included.

It has been customary to assign similar electron distributions² for the series of molecules CH_4 , NH_3 , H_2O and HF . As Ellison and Shull³ showed, hybridization does not necessarily determine the molecular geometry for H_2O . More recently, Bader and Jones⁴⁻⁶ have seriously questioned even a suggestion of similarity by observing that the lone-pair electrons in their calculations possess the maximum amount of s character. It seems qualitatively useful to compare the polarization of the valence shell for the various calculations on these molecules.

The calculations of Pople and Duncan⁷ on NH_3 , H_2O and HF are frequently quoted to support the concept of directed lone-pairs. If the electron distribution of NH_4^+ is similar to NH_3 , the valence shell of nitrogen must be polarized to substitute for the removal, and the associated polarizing effect, of a proton. Since it seems natural to define positive polarization along the symmetry axis towards the protons, this polarization is negative. In Table 1, the polarizations extracted from the calculations of Pople and Duncan⁷ are given. Bond polarizations are also given, but since these contain other hybridizations only the sign is pertinent.

Molecule	Table 1 Shell polarization	Bond polarization
NH ₃	-0.93	0.037
H ₂ O	-0.86	0.071
HF ($\beta = 95^\circ$)	-0.56	0.286
HF ($\beta = 116^\circ$)	-0.52	0.105

Since, as Mulliken¹ showed, positive bond polarization is conducive to larger overlap, this might compensate for the comparatively large negative polarization. Although the expectancy of negative shell polarization is reasonable for molecules with lone-pair electrons, the same expectancy for at least positive bond polarization is not realized in recent calculations. For example, bond polarization for HF is negative in recent work (for example, -0.27 (ref. 8), -0.46 (ref. 6)) as it is for the shell polarization (for example, -0.46 (ref. 8), -0.25 (ref. 6)). The principle of maximum overlap⁹ is obviously not a good criterion for these molecules.

There is some justification to write the equivalent orbitals for methane to a good approximation in the form:

$$\psi_i = \lambda[\cos \varepsilon_b (2s) + \sin \varepsilon_b (2p_i)] + \mu\psi_i$$

where $2p_i$ is an STO defined with its axis along a line connecting carbon and the i^{th} proton. The bond polarization is certainly positive in this case. This type of polarization is reflected by an expansion or contraction of the valence shell on bond formation. This possible difference in sign of the bond polarization between methane and hydrogen fluoride suggests that overlap is not of the same importance in these two molecules. In Table 2, a comparison of selected calculations on water is given. Strict comparison is not possible owing to the different requirements that the different electron densities reproduce.

Reference	Table 2 Shell polarization	S/S_0	ψ l.p.
7	-0.87	2.34	0.791 (2s) - 0.612 (2p _z)
3	-0.54	1.87	0.962 (2s) - 0.272 (2p _z)
5	-0.28	1.6	(2s)
11	0	1	0.492 (2s) + 0.871 (2p _z)

ψ l.p. is one of the lone-pair orbitals, the other being the $2p_z$ STO, and S_0 is the overlap integral S for the zero polarization case. All but the first calculations indicate negative bond polarization.

A number of points for discussion derive from Table 2. As shell polarization becomes less negative, so the overlap decreases. If we maintain that large polarizations are energetically unfavourable, it seems that the lone-pair electrons must be involved in the bonding. Bader¹⁰ has already reached this conclusion, but prefers to use the term 'binding' rather than 'bonding'. However, whether binding, for lone-pair electrons, or bonding, for bonding electrons, both are functions of the energy. There does not seem to be any convenient way to determine a value for the shielding so that a comparison with the overlap can be made. Bader has plotted the difference between a proposed molecular density distribution and one obtained from the original atomic densities centred on the same nuclear configuration, to show, in the case of water, that for small polarizations (-0.28) there is an excess charge build-up in the binding region for the molecule. Significantly, there is charge loss in this region for large overlap (-0.87). The binding region is within the H-O-H triangle, the region where the lone-pair electrons are concentrated for small polarizations (see Table 2). Obviously, the more positive the polarization, the more lone-pair electron density will be put into the binding region. Unless we know the relative importance of each term and the effect on the energy, further qualitative discussion is purely speculative. However, it appears that a small amount of negative polarization for the valence shell is reasonable. The actual amount will depend on the geometry of the molecule and the number of lone-pair electrons (NH₃ -0.34 (ref. 4); H₂O -0.28 (ref. 5); HF -0.25 (ref. 6)).

Some of the more pertinent conclusions are: (a) the long-range electrostatic fields involved in molecules with

lone-pair electrons may invalidate the localized bond approach dependent on the principle of maximum overlap; (b) the shielding of the lone-pair electrons in the binding regions of the molecule can more than compensate for loss in the overlap of atomic orbitals involved in bonding; (c) in terms of orbitals so important to chemists' theories of electronic structure the principle of 'A little polarization goes a long way' seems to be important for the valence shell of atoms containing lone-pair electrons. I thank Dr. K. E. Banyard for his advice.

Breakdown of Simple Hydrocarbons subjected to a Silent Electric Discharge

THE gassing tendencies of insulating oils used in the electrical industry are assessed by measuring the rate of gas evolution or absorption when they are exposed under an atmosphere of hydrogen in an electrodeless discharge tube of the Siemens Evers-type. Previous investigations¹⁻⁴ have been confined to the investigation of a wide variety of commercial oils and the effect of additions of aromatic rich oil fractions and other additives chosen for their ability to impart a desirable hydrogen gas absorbing characteristic to the mixture. The different hydrocarbon types present in the oils, paraffins, naphthenes, olefines and aromatics cause the discharge reaction to be a complex competitive process in which the gas evolved by the paraffins and naphthenes is partially or completely absorbed by the olefinic and aromatic fractions. To avoid this complexity and enable a clearer understanding of the reaction processes to be reached, certain pure saturated and unsaturated hydrocarbons representative of the types found in oils have been selected for investigation. The experiments have shown that the discharge reaction is closely related to the corresponding radiolytic breakdown of simple hydrocarbons⁵.

A new design of gassing cell (Fig. 1) was used to measure the gassing rates. No radical change has been made in the basic design, since the concentric electrode system, a feature common to most other cells, has been retained. The design is such that hydrocarbons can be saturated with hydrogen after being transferred to the cell. Similarly, the more rigorous pre-treatment involving degassing at a pressure of a few microns prior to saturation with hydrogen gas, necessary for the more viscous commercial oils, can be carried out on the sample in the cell. In this way all risk of contamination with air or grease from taps and joints is avoided. The rate of gas evolution or absorption is followed by observing the rise or fall of the liquid under test in the central manometer tube.

After saturating the hydrocarbon with hydrogen by bubbling the gas through the liquid for 5 min at the test temperature, maintained by a metal heating block, a stress, calculated to be 43 kV/cm in the un-ionized gas phase, was applied at a voltage of 12 kV root mean square. Two distinct types of behaviour were observed. The saturated hydrocarbons, both straight-chain and ring structure, evolved gas at a constant rate, while the unsaturated hydrocarbons, including benzene, absorbed gas at a constant rate, after the first few minutes of

Table 1. GAS EVOLUTION AND ABSORPTION RATES FOR SIMPLE HYDROCARBONS

Saturated hydrocarbons	Rate of gas evolution ml./min	Unsaturated hydrocarbons	Rate of gas absorption ml./min
Cyclohexane	0.020 ± 0.001	1 decene	0.047 ± 0.001
Decane	0.013	1 octadecene	0.016
Hexadecane	0.006	1.19 eicosadiene	0.010
		Benzene	0.012

The rates were measured at 40° C using an applied voltage of 12 kV which gave a calculated stress of 43 kV/cm in the un-ionized gas phase.

reaction. Values of the rates obtained at 40° C are shown in Table 1. Vapour-phase chromatographic analysis of the gaseous products from *n*-decane showed that the major product was molecular hydrogen (96.4 per cent) while the remainder consisted of methane, ethane, propane and butanes. The main reaction must therefore be the production of molecular hydrogen by C—H scission while some C—C scission occurs yielding the small quantities of lower-molecular-weight hydrocarbons. This suggests that the reaction is similar to that observed in the radiolytic breakdown of liquid hydrocarbons⁶ where the molecular hydrogen yield has been accounted for by regarding the dominant reaction as the formation *in situ* of hydrogen atoms which then take part in competitive abstraction and addition reactions. Gas evolution rates for the discharge reaction of the saturated hydrocarbon

Fig. 1. Diagram of new British Insulated Callender's Cables, Ltd., gassing cell

Fig. 2. Rate of gas evolution from decane-decene mixtures stressed under hydrogen at 60° C, 12 kV

Fig. 3. $1/R_{\text{decane}} - R_{\text{mixture}}$ versus (decane)/(decene)Fig. 4. Arrhenius plots for the reactions of *n*-decane (x) and 1 octadecene (O) stressed at an applied voltage of 12 kV

n-decane and mixtures containing low concentrations of the congruent unsaturated hydrocarbon 1-decene obey the same form of kinetic equation as that proposed for the radiolysis process⁷:

$$\frac{1}{R_{\text{decane}} - R_{\text{mixture}}} = A \frac{(\text{decane})}{(1\text{-decene})} + C$$

where *R* represents the rate of gas evolution measured in ml./min and *A* and *C* are constants (Figs. 2 and 3).

A slow stream of hydrogen gas, passed through an empty cell, the inner electrode of which had been previously dusted with molybdenum trioxide, reduced this oxide to the blue oxide when the electric stress was applied. This confirms that atomic hydrogen is formed in the gas phase under discharge conditions and affords further evidence for the suggested reaction mechanism.

Arrhenius plots of rate against absolute temperature (Fig. 4) for 1 octadecene and *n*-decane gave values of 2.5 kcal/mole and 2.9 kcal/mole for the respective activation energies, values about eight times those for the radiation-induced reactions in hydrocarbons.

These experiments suggest that the discharge reaction is explicable in a similar way to the radiolytic reaction, although the existence of a gaseous phase, a gas liquid interface and the lower energy of the electric discharge give rise to different reaction conditions, such that thermal collision processes are more prominent, as is evident from the higher activation energies. By examining other hydrocarbon mixtures and working under different gas atmospheres at different temperatures, it is

hoped to elucidate the reaction mechanism further and calculate absolute rate constants for comparison with those obtained radiolytically.

I thank Dr. A. L. Williams, director of research and engineering, British Insulated Callender's Cables, Ltd., for permission to publish this communication, and Dr. R. M. Black and Mr. E. H. Reynolds for their advice.

BIOCHEMISTRY

Molecular Weight of Urokinase

UROKINASE is a proteolytic enzyme in human urine¹. Its ability to activate plasminogen has stimulated interest in its potential clinical use as a thrombolytic agent.

Investigations were initiated in this laboratory to further characterize urokinase. Purified preparations of urokinase of specific activity approximately 7,000 Ploug units/mg dry weight (ref. 2) were obtained from Leo Laboratories (London) and other samples used were prepared from human urine. As a crystalline urokinase of about 100,000 C.T.A. units/mg protein (1 C.T.A. unit (ref. 3) = 0.7 Ploug units) has been described⁴, the material we have employed cannot be regarded as pure.

We have estimated the molecular weight of urokinase by a gel-filtration method⁵. Columns of 'Sephadex G-75' and 'G-100' were prepared and the elution volumes determined for a number of pure proteins by monitoring the ultra-violet absorption of the column effluent. The buffer routinely used was 0.05 M *tris*-HCl (pH 7.5) containing 0.1 M potassium chloride. Proteins used for calibration of the columns were cytochrome C, ribonuclease, myoglobin, soya-bean trypsin inhibitor, α -chymotrypsinogen, β -lactoglobulin, ovalbumin, serum albumin and γ -globulin. The relation between elution volume and \log_{10} mol. wt. was linear over the molecular weight-range investigated (12,000–70,000) for both columns (Fig. 1).

The elution volume of various urokinase samples was determined on both 'G-75' and 'G-100 Sephadex' columns. As it was known that the enzyme preparation was impure, detection of protein in the column effluent by ultra-violet absorption was not used. Instead, the urokinase

Fig. 1. Molecular weight calibrations of columns of 'Sephadex G-75' and 'G-100' at pH 7.5. 'X' indicates the position on the lines corresponding to the elution volume of urokinase

Fig. 2. The elution profile of a sample of urokinase on 'Sephadex G-100' at pH 7.5

present was assayed by its ability to activate plasminogen using the fibrin plate method². The elution volume obtained on 'G-75 Sephadex' was 114 ± 2 ml. and on 'G-100 Sephadex' was 138 ± 2 ml. (Fig. 2). In each case this corresponds to a molecular weight of $34,500 \pm 2,000$ for urokinase.

Evidence that some urokinase samples were contaminated with a small quantity of high-molecular-weight material capable of activating plasminogen was observed; but the possibility that this represents urokinase bound to a high molecular weight material could not be excluded. This material was completely excluded from both gels and therefore had a molecular weight of at least 100,000. No contamination of the urokinase by other proteolytic enzymes of less than 100,000 molecular weight was observed.

In order to minimize the possibility of the observed urokinase elution volume being modified by absorption effects, a similar experiment was performed using a 'G-75 Sephadex' column equilibrated with borate buffer at pH 10. An experiment was also performed on 'G-100 Sephadex' at pH 7.5 in the presence of 0.7 M potassium chloride instead of 0.1 M potassium chloride. In neither case was any change observed in the estimated molecular weight of urokinase.

These experiments indicate that the molecular weight of urokinase is approximately 35,000. This is much lower than the value of 53,000 recently reported for a crystalline sample of urokinase by Lesuk *et al.*⁴, based on ultracentrifugation measurements. The reason for the discrepancy between these two estimates is not clear.

Localized Strand Separations within Deoxyribonucleic Acid during Selective Transcription

MOLECULES of deoxyribonucleic acid isolated under gentle conditions are found to possess a double-stranded helical structure, in which the bases of each DNA strand are exactly paired within the interior of the helix with

complementary bases of the opposite strand¹. During gene transcription *in vivo* or under gentle conditions *in vitro*, only one of the two DNA strands serves as a template for new RNA synthesis². Furthermore, within a well-differentiated tissue, only a fraction of loci within the total genome are transcribed *in vivo*, each such selection of loci being characteristic of the particular tissue³. It has recently been demonstrated that stable localized strand separations are induced within the double-stranded DNA helix during selective gene transcription within higher organisms^{4,5}. Within such localized separation loops, one DNA strand appears to function as a template for RNA synthesis⁵. The complementary DNA strand of each separation loop appears to function as a binding site for specific de-repressor RNA molecules⁵ in an epigenetic control mechanism which selectively restricts gene transcription to only such strand-separated portions of the genome^{5,6}.

During cell interphase in higher organisms, the DNA molecules of the cell nucleus are found arrayed either within condensed masses of heterochromatin^{7,8} in which RNA synthesis is repressed⁷⁻⁹, or within extended microfibrils of euchromatin^{7,8} in which RNA synthesis is active⁷⁻⁹. When such repressed-heterochromatin and active-euchromatin complexes of a single tissue are each isolated in parallel under identical gentle conditions⁷, the isolated heterochromatin retains its original repressed and condensed state⁴, while the isolated euchromatin retains its original active and extended state⁴. The native associations between DNA and the other molecular species of chromatin, such as repressor histones, de-repressor RNA, and endogenous RNA polymerase, have been examined within isolated heterochromatin and isolated euchromatin in a variety of physical, chemical, and metabolic investigations^{4,6}.

DNA molecules isolated from either type of chromatin of one tissue are not significantly different in their base composition^{4,6} or in their thermal denaturation profiles⁴. Similarly, both types of chromatin contain the same quantities and patterns of histones in relation to their DNA contents^{4,6}. By contrast, active euchromatin contains an excess of such nuclear polyanions as RNA⁴, phosphoproteins¹⁰, and phospholipids¹¹, and localizes testosterone during stimulation of RNA synthesis by this steroid hormone¹².

When DNA molecules are examined while within the active euchromatin complex, they display a 60 per cent reduction of their usual thermal hyperchromicity⁴, indicating a significant degree of separation of the strands within their DNA double helices^{5,6}. By contrast, such DNA molecules of the sample display an entirely normal degree of thermal hyperchromicity when they are first isolated away from the histones and polyanions of the euchromatin complex before being examined⁴. Such contrasting behaviour suggests that the DNA strand separations observed within the intact euchromatin complex depend on an association with the other molecular species of euchromatin for the stabilization of such strand separations^{5,6}. The regaining of normal hyperchromicity following DNA isolation also suggests that these strand separations are only partial or looped within any given DNA double helical molecule, with some portion of each helix remaining in exact register during selective gene transcription^{5,6}. In parallel investigations under identical conditions, the DNA molecules while within the repressed heterochromatin complex do not reveal any reduction of their usual hyperchromicity⁴, but display an increased stability to strand separation while within the heterochromatin complex⁴.

Both active euchromatin and repressed heterochromatin contain equal amounts and types of polycationic histones in relation to their polyanionic DNA^{4,6}. Such histones function as non-specific repressors of the template function of DNA by interacting electrostatically with the negative phosphate groups on the exterior of the DNA double

helix^{13,14}. This histone-DNA interaction neutralizes the multiple negative charges along the length of the DNA molecule^{13,14}, overcoming the mutual repulsion otherwise present between these highly charged DNA molecules¹⁵, and favouring the formation of condensed masses of repressed heterochromatin^{6,16}. In such an interaction, the histones cross-link two or more DNA strands¹⁷, thus stabilizing the double-stranded DNA helices against strand separation and consequent transcription¹⁸.

The polycationic histone repressors can be partially displaced from the DNA double helices by several types of those polyanions found in excess within active chromatin⁴. In such action, these polyanions function as natural de-repressors, permitting the now-charged DNA double helix to assume the extended state⁶ and to undergo its normal degree of spontaneous strand separations¹⁹. Strand separation loops formed spontaneously appear to be stabilized and perhaps extended within specific loci of the genome by the co-operative binding of specific de-repressor RNA molecules to one of the two separated DNA strands at these loci^{5,6}. The remaining complementary DNA strand within the separation loop is then free to serve as a template for selective RNA synthesis^{5,6}.

These investigations indicate that the physical state of the DNA molecules during selective transcription in higher organisms is characterized by local stabilized separations of the strands of the DNA double helix within specific portions of the genome⁵. By contrast, repressed portions of the genome are characterized by an increased stability of the DNA helix⁴, with no evidence of strand separations⁴ or of active transcription^{7,9}, and appear as condensed masses of heterochromatin during cell interphase^{7,8}. Later in the cell cycle, during DNA replication, these same repressed heterochromatin portions of the genome display a late phase of DNA synthesis compared to the rest of the genome²⁰. Since *in vivo* DNA replication involves some degree of strand separation of the replicating DNA molecules²¹, the delay in DNA replication observed within these repressed heterochromatin regions may reflect the increased stability of the DNA helices within these regions found earlier in the cell cycle during selective transcription⁴.

Still later in the cell cycle, after the completion of DNA replication, these same repressed heterochromatin regions of the genome²² may now extend and form secondary constrictions²³ in localized areas of the metaphase chromosomes²². Such secondary constrictions map identically within each of the sister chromatids²³, indicating that each daughter cell receives an identical complement of chromosomes the DNA of which is physically altered in those same gene loci that were repressed in transcription and delayed in replication in the maternal cell⁶. Indeed, following cell division, it has been shown that at least some of the same gene loci that were repressed for transcription in the maternal cell are similarly repressed in each of the daughter cells for many subsequent cell generations²⁴, indicating a continuity of the specific transcription selection through the entire course of many cell divisions⁶. Such a continuity could be mediated by the passive symmetric transfer of maternal de-repressor RNA species to each of the daughter cells during cell division^{6,25}.

The strand separation loops within the DNA molecules of active euchromatin are the likely sites of action of those molecular species which increase or decrease the rate of RNA synthesis non-specifically⁶. Thus, such steroid hormones as oestradiol and testosterone bind preferentially to the single-stranded form of DNA²⁶, tending to stabilize the strand separation loops within DNA²⁶, and non-specifically increasing the rate of RNA synthesis within pre-selected loci of the genome²⁷. In this regard, testosterone is found localized preferentially within active euchromatin during the stimulation of nuclear RNA synthesis by hormone¹². Conversely, such inhibitors as histones¹⁴, actinomycin D²⁸, acridine orange²⁹, and chloroquine³⁰ all bind preferentially to the double-

stranded form of DNA, tending to stabilize the DNA helix against strand separations, and non-specifically decreasing the rate of synthesis of all RNA species⁶.

Recent investigations suggest that the strand separation loops within active euchromatin may be sensitive sites of action during radiosensitization³¹ and during the interaction of the host genome with oncogenic viruses³².

This work was carried out during the tenure of a research career development award (CA-17857) from the U.S. Public Health Service.

Properties of Hyaluronic Acid from a Human Myxosarcoma

It is known that the degree of polymerization of purified hyaluronic acid depends on the sources of preparation and the method of isolation. Caputo and I previously reported¹ the occurrence in Rous sarcoma of highly polymerized hyaluronic acid complexed with protein. Investigations of the effect of proteolytic enzymes on this complex have revealed the prominent part played by the protein in the molecular conformation of the complex².

This communication reports some properties of a very special hyaluronic acid which I have purified from a human myxosarcoma.

The polysaccharide was isolated by precipitation with cold, acid acetone, according to the technique previously

Table 1. MOLECULAR CHARACTERISTICS OF A HYALURONIC ACID-PROTEIN COMPLEX ISOLATED FROM HUMAN MYXOSARCOMA

$S_{20,w}^*$	16.8×10^{-13}
$D_{20,w}^\dagger$	5.7×10^{-7}
\bar{V}	0.710
Mw	2.5×10^5

* Extrapolated to zero protein concentration.

† Protein concentration 5 mg/ml.

reported¹. At the end of the preparation several further attempts to reduce the nitrogen content of the compound failed, and therefore it seemed certain that the polysaccharide was stably complexed with a protein. The resulting material behaved as a monodispersed system in the free boundary electrophoresis and was homogeneous in the ultracentrifuge. When compared with other types of hyaluronic acid, the sedimentation boundary of the myxosarcoma polysaccharide was always found to be perceptibly less sharp and to have a great tendency to diffuse. Some molecular characteristics of myxosarcoma hyaluronic acid-protein complex are given in Table 1.

The molecular weight of 2.5×10^5 is very low compared with values of about 1 million described previously for the same polysaccharide isolated from different sources.

After treatment with hyaluronidase, a decrease in the viscosity of the hyaluronic acid complex solution and the disappearance in electrophoresis and the ultracentrifuge of the homogeneity of the boundary were observed.

Preliminary chemical analyses have shown that the protein content of hyaluronic acid complex from myxosarcoma is about 45 per cent. Until now this value is the highest found for all types of hyaluronic acid-protein complex.

The fact that proteolytic enzymes have a very weak effect on the hyaluronic acid complex from myxosarcoma provides strong evidence that the polysaccharide occurs in this tumour in a completely different molecular state, not only from that isolated from normal sources, but also from Rous sarcoma. Stronger evidence for this hypothesis has been provided by additional chemical analyses of the amino-acid composition of the protein moiety of the complex. In this connexion it is interesting to note that hydroxyproline was found in the hydrolysate, among seventeen different amino-acids. The fact that myxosarcoma hyaluronic acid containing hydroxyproline has a low molecular weight indicates that there is a similarity between this polysaccharide and that already isolated from vitreous humour and that it is completely different from that previously isolated from the Rous sarcoma.

Oleic Acid labelled with Iodine-131, and Triolein De-iodination *in vitro*

THE de-iodination of ¹³¹I-labelled Rose Bengal¹ and thyroxine² has been studied before, and it can be assumed that a thermostable factor is present in the organs in different concentrations³ and that some proteins⁴ have a stimulative effect on the de-iodination.

This experimental work was carried out to study the de-iodination *in vitro* of ¹³¹I-labelled oleic acid and triolein, widely used as diagnostic radiopharmaceuticals. Some variable results obtained in the investigation of fatty-acid metabolism with these radioisotopes could be related to the de-iodination *in vivo*⁵.

The tested rat organs were homogenized with saline to give a final organ concentration of approximately 200 mg/ml. (wet organ weight). Three series of experi-

Fig. 1 Iodine-131 found as iodide after 15 h incubation 1, ¹³¹I-labelled triolein; 2, ¹³¹I-labelled oleic acid

ments using ¹³¹I-labelled triolein (specific activity 29 μ c./mg) and three other series using ¹³¹I-labelled oleic acid (specific activity 38 μ c./mg, were performed. 10 μ l of the labelled compound (approximately 50 μ c.) were added to each series of test-tubes containing 0.5 ml. of homogenate and 0.2 ml. of isotonic phosphate buffer, pH 7.2. In each series a test tube containing the same activity in 0.2 ml. of isotonic phosphate buffer pH 7.2 and an equal volume of saline instead of the homogenate were used as a blank. All the tubes were incubated under the same conditions: 15 h at 37° C with occasional stirring and avoiding the evaporation.

After the incubation was completed, 2 ml. of ethyl alcohol was added to each tube and then stirred and centrifuged. The residue was washed once with 1 ml. of ethyl alcohol and finally extracted twice with 1 ml. of ethyl ether. The alcohol and ether extracts were mixed and a sample of it was analysed by paper electrophoresis. Under these experimental conditions the formed iodide as well as the labelled oleic acid or triolein are completely extracted from the tissue residue.

The electrophoresis was performed using Whatman 3 MM paper, sodium bicarbonate, 0.2 per cent, as a buffer and with a voltage gradient of 12 V/cm. After 1 h the iodide migrated approximately 6 cm while the labelled triolein or oleic acid remained at the starting line.

The scanning of the electrophoresis was carried out using an automatic graphic recorder. In this way it was possible to evaluate, by integration, the percentage of activity corresponding to each peak (iodide and labelled oleic acid or triolein; no other intermediate compound was detected). Fig. 1 gives the values corresponding to the formed radioiodide (as percentage of the total activity present) after 15 h of incubation at 37° C. No iodide formation was found in the blank test-tubes.

The ¹³¹I-labelled oleic acid was rapidly de-iodinated by liver and blood homogenates; the ¹³¹I-labelled triolein was more stable. Intestine was twice as active for ¹³¹I-labelled triolein as for ¹³¹I-labelled oleic acid. The stomach had practically no action on ¹³¹I-labelled triolein and ¹³¹I-labelled oleic acid *in vitro*.

As a result of these experiments it can be stated that the blood and liver are rich in the dehalogenase responsible for the de-iodination of both labelled compounds.

PHYSIOLOGY

Heat Production in a Cardiac Contraction

THE energetics of cardiac contraction, a field of much physiological interest, has remained incompletely developed because of the difficulty of performing heat measurements on a heart muscle preparation. We have recently succeeded in solving some of the technical difficulties and have developed a procedure for myothermic measurements on isolated papillary muscles of the rabbit heart.

The papillary muscles used are about 1.0 mm in diameter and 4–8 mm in length. To obtain an adequate thermopile output, a sufficient number of junctions has to be situated in this range of lengths. The present pile has 32 active and 4 'protective' junctions of silver constantan over a length of 5 mm; it has an output of 815 μ V/°C. The junctions are situated at the bottom of a hemicylindrical trough, about 1 mm diameter, that holds the muscle.

The problems associated with myothermic measurements have been discussed in detail by Hill^{1–3}. A major difficulty encountered with cardiac heat measurements is the large heat capacity of the thermopile relative to that of the small muscle. This heat capacity was determined, on the one hand, by liberating a condenser discharge or an RF current pulse into a saline-gelatin rod placed in the thermopile groove; on the other hand, using the cardiac pile, measurements were made on a 20-mg strip carefully dissected from a frog sartorius muscle on which heat measurements had previously been made with a standard thermopile. Both methods agreed; the present thermopile has a heat capacity equivalent to 3.0 ± 0.5 mg of muscle. The muscles themselves generally weigh 3–10 mg. The average heat loss from the muscle-thermopile system is 13 per cent per second; this is corrected for electronically. The correction method and the technique for thermopile construction will be described by one of us (N. V. R.) in a later paper. The muscles were bathed in a modified Tyrode solution containing 4.0 mM calcium/l. and aerated with 98 per cent oxygen and 2 per cent carbon dioxide. The experiments were run at room temperature which was between 18 and 22° C. The muscles were not left out of solution longer than 15 min and were never stimulated at frequencies above 60 beats/min.

In the work recorded here we have concerned ourselves solely with the magnitude of heat production, and some of the results obtained are given in Table 1. Our main objectives were to determine: (1) the rate of resting heat production; (2) the relationship between heat production and tension development; (3) if there was a heat equivalent to the activation heat of skeletal muscle. Resting heat was measured by first zeroing the amplifier input with the thermopile immersed in solution. The papillary muscle was then brought into contact with the pile and the change in input voltage was measured when the bath was drained of Tyrode solution. The heat output was measured over a period of several minutes. The experiments were all run with a resting tension of 1.0 g on the muscle and hence the measurement makes no distinction between the basal resting heat and the heat due to the existence of tension in the resting muscle⁴. The mean value of seven individual measurements was 25.7 mcal/g muscle/min.

Table 1

Exp. No.	Blotted weight (mg)	P ₀ — M	P ₀ — H	Resting heat (mcal/g/min)	Activation heat (mcal/g/twitch)	Heat* (mcal/g/twitch)	Tension (g)
1	5.0	433	4.05	—	—	1.59	3.3

* Tension and heat measured in a single contraction after a period of stimulation at 30 beats/min.

Records of heat produced during a cardiac contraction are shown in Fig. 1. The rate of heat production seems to be much slower than in skeletal muscle, but at present we cannot be certain that this is not an artefact. The muscle was first stabilized at a chosen frequency. Stimulation was then stopped; the heat quickly returned to its resting level. A single stimulus given at this point gave a tension output similar to that in the steady state and the heat produced was measured a few seconds after the contraction was completed. The heat production so measured was 10–20 per cent less than that determined from the total heat produced in a long series of contractions divided by the twitch number. There can be at least two reasons for this: (1) the resting heat production may increase during prolonged activity, a possibility suggested by Whalen⁶ in his oxygen consumption studies, or (2) there may be a small and slow phase of delayed heat that we miss by reading too early after a single contraction. To investigate this point we need a thermopile with more output and one that possesses an accurate exponential heat loss over several minutes. The relationship between isometric tension and the heat produced can either be curvilinear as shown in Fig. 2 or linear, and seems to resemble skeletal muscle in this property⁶.

Activation heat was determined either by allowing the muscle to shorten until little or no active tension was developed on stimulation⁷, or by eliminating tension development with Tyrode solution made hypertonic with sucrose⁸. The mean of six such measurements was 0.6 mecal/g.

The results so far obtained allow interesting preliminary comparisons to be made to frog sartorius muscle. The lesser

activation heat, 0.6 as compared with 1.2 mecal/g (ref. 9), possibly correlates with the lesser capability for tension development. The slower rate of heat production in a twitch, if confirmed, might have a two-fold cause: the slower onset of the active state¹⁰, and the fact that the aerobic recovery heat is presumably not a separate entity but occurs in close temporal association with each twitch to which it belongs. The latter circumstances would also explain why the ratio P/H is 5.2 rather than close to 10 as found by Hill¹¹.

We thank Dr. W. F. H. M. Mommaerts for his advice.

Somesthetic and Visual Responses of Superior Colliculus Neurones

APART from visual responses¹, somesthetic responses have been repeatedly observed in the superior colliculus². We have previously reported that under chloralose anaesthesia the somesthetic responses to forelimb stimulation recorded with gross concentric electrodes could be divided into a short-latency group (9 ms) and a long-latency group (70 ms), and that long-latency responses disappeared after ablation of the visual cortex³. This indicated a convergence of two somesthetic pathways towards the colliculus, as well as a convergence of somesthetic and visual afferent pathways. A microelectrode analysis has

been undertaken in order to determine the extent of these convergences at the cellular level.

Cats were anaesthetized with chloralose (80 mg/kg) administered intravenously, placed in a stereotaxic head holder and later paralysed with 'Flaxedil' and artificially respired. A hole drilled in the skull over the visual cortex, plugged with a 4-per cent solution of agar to reduce the pulsations of the brain, allowed the penetration of capillary microelectrodes filled with 3-M potassium chloride. Punctures were made only in the central part of the superior colliculus, mostly along the line A2, L3, from $H + 4.5$ to $H + 2.5$ to the zero plane⁴, thereby avoiding the insecurity in studying responses near the margins of the nucleus. Stimulation of the contralateral eye was a 500-ms flash obtained from a neon tube. The pupil was dilated with 1 per cent atropine chloride. Electrical stimuli were delivered to each of the four limbs through a pair of hypodermic needles thrust into the skin. At the end of the experiment the brain was perfused with saline, followed by 10 per cent formalin, and the approximate locations of the electrodes tips were checked in frozen sections.

Extracellular records were analysed in 82 units, all of which maintained a constant spike height and responded to at least one of the stimulations used.

Somesthetic responses were observed in 79 of the 82 cells examined. These responses showed short or long latencies. In both cases they were characterized by slow waves that after their onset gave rise to a burst of spikes (usually two or three but sometimes more). With forelimb stimulation the onset of the slow wave for short and long latency responses began after 9 ms and 68 ms respectively. It may be appreciated that the values for latencies of the slow waves are similar to those of responses recorded with gross concentric electrodes. The mean average latency of the first spike for the short-latency responses was 18 ± 5 ms (forelimb stimulation) and 23 ± 5 ms (hindlimb stimulation), and for long-latency responses was 72 ± 12 ms (forelimb stimulation) and 81 ± 12 ms (hindlimb stimulation). The histogram in Fig. 1 shows the distribution of latencies of the first spike of response appearing with short and long latency in a series of collicular neurones. Among the 79 units included in the histogram of Fig. 1, 18 responded only with a short latency (Fig. 1a); 47 responded only with a long latency (Fig. 1c) and 14 responded with a double response, in which the latencies of the two components fell within the range of the two previous groups (Fig. 1b). Somesthetic units belonging to the various groups already described here may be indistinctly found at variable depths of the superior colliculus. However, more than half of the short-latency responses (including those followed by a long-latency one) were encountered in the lowermost third of the superior colliculus (Fig. 2). This finding may suggest some degree of topographical distribution of these different types of cells along the vertical axis. Sections of the spinal dorsal funiculi at the level of T8 did not modify the responses to stimulation of any leg. On the other hand, ablation of the visual cortex and surrounding cortical areas above the colliculus suppressed the long-latency ones.

These results confirm that the superior colliculus receives two independent groups of somesthetic impulses: one of these groups seems to depend on a relay in the visual cortex, and thus on cortico-collicular connexions; the other one is probably conveyed by the spinotectal pathway. In addition, it is apparent that a large number of collicular neurones receive a convergent input from these two pathways.

Visual responses were observed in 72 of the 82 units investigated. As already observed by Altman and Malis¹ some units responded to light-on, others to light-off, and still others to light-on and to light-off. Among the 10 units which apparently responded only to somatic stimuli, activating and inhibiting effects of light could be demon-

strated when tested on a response to somesthetic stimulation. These effects were independent of the type of somesthetic response one (short-latency, long-latency or double).

Considering the whole sample of neurons studied, it can be seen that only 3 units responding to visual stimuli were not activated by somesthetic stimuli, and 4 were in the reverse situation. The other 75 units received visual and somesthetic inputs. Once again the distribution of the neurons along the vertical axis did not seem to be correlated with their responsiveness to somatic or visual stimuli (Fig. 2).

Thus at the cellular level there is a high degree of convergence not only between the two somesthetic pathways, but also between the somesthetic and visual pathways. Since the colliculus has a dual visual input^{1,5} (some impulses reaching it directly from the retina, others relating in the visual cortex), a part of the observed

Fig. 1. Histograms of latencies of superior colliculus units to somesthetic stimulation. The abscissa corresponds to the latencies of the responses in msec and the ordinate to the number of units discharging at given latencies. Two populations of cells according to their latencies are clearly shown by the histograms. The units responding with both short and long latency are included in both histograms. Latency for each unit is average for stimulation of all four extremities. *n*, Number of units studied in each group. The upper figures give examples of the firing of each type of unit: (a) cell firing only with short latency; (b) with both short and long latency; (c) with long latency alone. Calibration: 50 msec and 1 mV.

Fig. 2. Distribution of units in the superior colliculus. Histograms represent the number of units recorded at different levels of the superior colliculus expressed according with the type of stimulation (visual or somesthetic) and the latency of somesthetic responses. White bands, units responding to visual stimuli; dotted bands, units responding with long-latency somesthetic responses; black bands, units responding with short-latency somesthetic responses. Units responding with both short and long latency to somesthetic stimuli were included in both dotted and black bands. The number of each type of units is expressed at the top of each band. The levels correspond to stereotaxic co-ordinates.

convergences can occur in the visual cortex. But another part must obviously occur in the superior colliculus itself, as, for example, the convergence between spino-tectal and retino-collicular impulses.

Anatomical studies⁶ have emphasized that retina and visual cortex project to more superficial collicular layers than spino-tectal fibres. Thus it is interesting to find so few 'modality-specific' neurones: that is, neurones responding only to visual or only to somesthetic stimulation. Further investigations, and especially, better localization of the electrodes tips, may tell if the 'specific' neurones were missed because of their small size or their anatomical localization. Perhaps another possibility might be that intracollicular connexions were responsible for the fact that nearly all collicular neurones studied received visual and somesthetic inputs.

I thank Dr. P. Ascher for his advice. This work was supported by a grant from the Consejo Nacional de Investigaciones Científicas y Técnicas, Argentina, and by grant AF-AFOSR-656-65 from the U.S. Air Force Office of Scientific Research.

PHARMACOLOGY

Thromboses in Large Veins and Pulmonary Embolisms induced by Catecholamines or Serotonin

It has recently been noted that a singular thrombohaemorrhagic phenomenon can be elicited in rats by the intravenous injection of various metals or sulphated polysaccharides (which act as 'sensitizers'), followed by subcutaneous treatment with catecholamines or serotonin (which act as 'challengers'). The basic structural lesions always consist of multiple haemorrhages and micro-thromboses, thus resembling those of the Sanarelli-Shwartzman phenomenon (induced by two properly spaced injections of bacterial endotoxins). In its simplest form, this thrombohaemorrhagic phenomenon is obtained by the intravenous administration of a sensitizer (for example, indium chloride) and the concurrent subcutaneous injection of a challenger (for example, adrenaline). In this case the lesions occur topically at the site of challenge; however, after similar sensitization, the systemic administration of suitable challengers can produce thrombohaemorrhagic lesions more or less selectively at various sites such as the salivary glands, heart, lung, kidneys, intestinal tract or even transplantable neoplasms¹⁻⁴.

The question arose whether this technique could be adapted to the production by naturally occurring compounds (such as catecholamines or serotonin) of experimental thromboses in large veins with subsequent pulmonary embolisms.

Eighty female Sprague Dawley rats with a mean initial body-weight of 100 g (90-100 g) were subdivided into eight equal groups and treated as indicated in Table 1.

Table 1. PRODUCTION OF VENOUS THROMBI BY SYSTEMIC SENSITIZATION WITH ScCl_3 AND TOPICAL CHALLENGE BY CATECHOLAMINES OR SEROTONIN

Treatment	Incidence (%) of thrombosis in femoral vein
NaCl	0
Adrenaline	0
Noradrenaline	0
Serotonin	0
ScCl_3 + NaCl	0
ScCl_3 + adrenaline	100
ScCl_3 + noradrenaline	100
ScCl_3 + serotonin	100

20 μg of adrenaline (adrenaline bitartrate, Brickman and Co.), 20 μg of noradrenaline ('Levophed' bitartrate, Winthrop Laboratories) and 200 μg of serotonin (serotonin creatinine sulphate, Nutritional Biochemicals, Ltd.) were used as challengers. All these amines were injected in 0.1 ml. of physiological saline into the musculature of the left thigh just underneath the femoral vein before its entrance into the inguinal canal. For control purposes, physiological saline was administered in the same manner. Scandium chloride (ScCl_3 , K and K Laboratories)—a particularly potent sensitizer for the production of het thrombohaemorrhagic phenomenon¹—was injected at a dose of 4 mg in 1 ml. water under light ether anaesthesia into the jugular vein 1 min before the administration of the challengers. All the animals were killed with chloroform 24 h later. The presence of thrombi was verified by inspection with a dissecting loupe and subsequent histological investigation of the femoral veins using the periodic acid-Schiff and multipurpose polychrome stains⁵.

As shown in Table 1, by itself the intramuscular injection of NaCl, adrenaline, noradrenaline or serotonin never produced thrombosis in the adjacent vein, while after sensitization with ScCl_3 all three biological amines (unlike the solvent itself) consistently gave positive results. The thrombi thus obtained were easily detectable by the naked eye (Fig. 1). They consisted of a white 'head' and a red 'tail'. On histological examination, the 'head' proved to be composed of aggregated platelet strands (Zahn's lines) surrounded by degenerating polymorphonuclear leucocytes; the 'tail' consisted of erythrocytes and fibrin threads. The 'heads' of the thrombi always pointed towards the heart and their composition was the same, irrespective of the challenger used.

The experiment was repeated afterwards under essentially similar conditions; but now the challengers were injected into muscles adjacent to the vena cava just distally from the origin of the renal veins. Here, large, almost occlusive thrombi of the cava were regularly

Fig. 1. Large thrombus occluding the left common iliac vein. The sharp line (arrow) dividing the white 'head' from the red 'tail' is clearly visible through the vessel wall.

Fig. 2. Large embolus exposed by reflecting the lateral wall of the right ventricle. The white 'head' is lodged in the tricuspid valve (long arrow) while the red 'tail' protrudes into the pulmonary cone.

obtained in the scandium-sensitized animals (but not in the controls) given adrenaline, noradrenaline or serotonin.

In a third experiment, thrombi were produced in the iliac veins of ten rats given the same amount of ScCl_3 intravenously and then adrenaline into the pelvic muscles adjacent to the left iliac vein. Twenty-four hours later, the injection site was exposed under ether anaesthesia through a suprapubic incision and the thrombi mobilized by gentle massage with the thumb applied to the thigh pushing towards the inguinal ligament. In each instance, the detachment of the thrombus and its propulsion into the vena cava could be followed by naked-eye inspection. Somewhat unexpectedly the resulting large emboli did not kill any of the rats, although autopsy of five animals 15 min after mobilization of their thrombi showed these firmly lodged in the almost totally occluded pulmonary artery (Fig. 2). In the remaining five animals, which were killed 24 h after the operation, the lysis of the pulmonary emboli was virtually complete.

In all these as well as in many similar experiments, it was incidentally noted that (irrespective of any additional treatment) after death the blood of rats sensitized with ScCl_3 clots in the vessels much more rapidly than that of normal controls. This is of interest in connexion with the currently popular view that the haemorrhages in various thrombohaemorrhagic phenomena—including the Sanarelli-Shwartzman reaction—are due to a "consumption coagulopathy"⁶. According to this concept the clotting factors are largely used up during the thrombotic phase, whereupon the blood gradually becomes incoagulable. This explanation does not appear to be easily applicable to the metal-induced type of thrombohaemorrhagic phenomena with which we are concerned here.

Labelled Depolarizing Drugs in Normal and Denervated Muscle

THE antagonism between *d*-tubocurarine and depolarizing relaxant drugs has been investigated by means of a decamethonium derivative labelled with radioactive iodine, the uptake of which in muscle is reduced in the presence of the antagonist^{1,2}. The present investigations have shown that *d*-tubocurarine also reduces the uptake of decamethonium and of carbachol which have been labelled with tritium, and, in addition, the muscles have been sectioned so that a localized concentration of drug in the region of the nerve endings could be demonstrated.

Fig. 1 shows the uptake of 6 μM decamethonium dichloride (*N*-methyl-³H) in isolated rat diaphragm. After 2 h at 38° C the muscle was removed, secured to a strip of aluminium and frozen on a block of solid carbon dioxide. The nerve could be seen in the frozen muscle. The tissue was trimmed with a razor blade to provide a rectangle of muscle, which was then sectioned transversely between tendon and rib at intervals of 1 mm. The sections were weighed, dissolved and counted by methods used previously³. The uptake in each section was expressed as ml./g. being (activity per g muscle)/(activity per ml. solution). The uptake shows a pronounced peak in the section which contained the nerve and a similar distribution was found in 20 muscles which were sectioned. The presence of *d*-tubocurarine in a concentration of 7 μM reduced the uptake as shown by the shaded portion of Fig. 1, though the peak was not entirely abolished even with high concentrations (up to 70 μM) of the antagonist.

The uptake of decamethonium by the phrenic nerve was found to be low and not affected by 7- μM *d*-tubocurarine, and the peak in Fig. 1 may be attributed to the presence of the endplates which are known to be in a narrow zone close to the nerve⁴. Decamethonium injected into mice has been shown to become localized in the endplates of the diaphragm muscle^{5,6}.

The unshaded part of Fig. 2 shows the uptake of labelled decamethonium in a diaphragm muscle of the guinea-pig, which is pharmacologically more sensitive to decamethonium than the rat⁷. In the guinea-pig the terminal branches of the phrenic nerve are not distributed in a regular manner. A flattened peak was found in all guinea-pig diaphragms which were sectioned, and this peak appeared to be abolished in the presence of a high concentration of *d*-tubocurarine (Fig. 2).

The light shading of Fig. 2 shows the uptake of decamethonium in a muscle which had been denervated 10 days previously by section of the left phrenic nerve in the thorax. The uptake is markedly increased, and a similar raised level of radioactivity was found in denervated muscle as compared with the control in each of 12 pairs of muscles which were tested. In most cases no peak could be demonstrated in denervated muscle. The increased uptake of the drug may be correlated with the

Fig. 1. Radioactivity of rat diaphragm cut transversely after 2 h in 6- μM labelled decamethonium. The uptake is given as ml./g. The section which contained the nerve is indicated by the arrow. The shaded area shows the uptake of another strip of muscle from the same diaphragm in the presence of 7- μM *d*-tubocurarine.

PATHOLOGY

Conversion of the Inconvertible L-1 Lymphosarcoma to Ascitic Form

DURING the course of experiments with the L-1 lymphosarcoma it was often desirable to have large numbers of single cells available. Suspensions of cells dissociated from minced tumour by standard techniques (cytosieve¹, trypsinization², etc.) contained variable numbers of morphologically dead cells and required large inocula ($\geq 10^4$ cells) to induce growth on subcutaneous re-inoculation. It seemed that the required numbers of free cells might be obtained if the tumour was converted to ascitic form. Following the method described by Klein and Klein³, cell suspensions prepared from the tumour by various techniques were intraperitoneally injected into strain A/J hosts. At graded intervals afterwards, the mice were killed, the open peritoneal cavity washed, and the collected washing re-inoculated into new mice. This was repeated for several fluid-transfer generations. In a course of more than twenty-five such attempts, a small growth of ascites was obtained in only a single instance. This one ascites grew slowly for three fluid-transfer generations and then failed to multiply on the fourth re-inoculation. In all other attempts, this procedure failed to produce ascitic growth. In many animals, however, nodular growths were obtained at the site of injection of the initial suspension, or on the peritoneal surface.

During the course of previous investigations in this laboratory, it was found possible to obtain relatively small numbers of highly viable tumour cells by trypsinization of minces of the liver and spleen, using the method described by Hewitt⁴. Comparable cell suspensions were also obtainable from the blood by modifications of the technique of Romsdahl *et al.*⁵. While neither of these techniques provided sufficient cells for certain of our requirements, it was reasoned that cells collected in this manner might be more amenable to the establishment of an ascites. Accordingly, a number of mice was injected with suspensions of cells collected in the foregoing two ways. In both groups, the peritoneal washings from almost all of the mice gave rise to the development of ascites when re-inoculated into new hosts.

Lines selected from these ascites have been serially transplanted at intervals ranging from 1 to 2 weeks for over one year and have continued to show good growth. Other lines, prepared by the same techniques, have also been successfully maintained for shorter periods. The ascites is composed predominantly of reproductively active cells, requiring somewhat less than ten cells on the average, to induce tumours in 50 per cent of previously untreated strain A/J mice (TD-50) when injected under the capsule of the kidney. The TD-50 for intraperitoneal injection is about an order of magnitude higher, while subcutaneous injection requires a yet larger inoculum. Although this aspect has not been examined in detail, it appears that the solid tumours resulting from the injection of ascites are morphologically similar to the original tumour and do not display any marked deviations in radiosensitivity, although they grow somewhat more rapidly. Interestingly, the lines initiated from circulating cells have consistently shown more rapid growth, both in solid and ascitic forms, than those started from cells obtained from the liver and spleen.

Of the various explanations for the foregoing results, a selection process seems most likely. Thus, cells which successfully enter the blood and which continue to circulate and, to a lesser extent, those which have travelled through the lymphatic or haematogenous circulation to lodge in the visceral organs, represent a selected population of cells which are better able to survive (and proliferate) in the free state. On the other hand, it may be that less mechanical damage occurs during the freeing of the cells

Fig. 2. The unshaded portion shows the uptake of labelled decamethonium in guinea-pig diaphragm treated as in Fig. 1. The dark areas show the uptake in another muscle in the presence of 70 μ M *d*-tubocurarine. The lightly shaded area shows the uptake in a muscle which had been denervated 10 days previously.

Fig. 3. Uptake of labelled carbachol in rat diaphragm (2 h in 1 μ M). The arrow indicates the section which contained the nerve. The shaded portion shows the uptake in another muscle which was treated with 7- μ M *d*-tubocurarine.

increased pharmacological sensitivity of denervated muscle^{6,7}. In similar experiments it was found that *d*-tubocurarine was also effective in reducing the uptake of labelled decamethonium in denervated guinea-pig diaphragm.

A localized peak was not found in the case of carbachol (carbaminoyle choline chloride, *N*-methyl-³H). Fig. 3 shows the uptake of labelled carbachol in rat diaphragm at a concentration of 1 μ M. The radioactivity of the muscle shows little variation from tendon to rib, and a similar distribution was found with concentrations of 5 and 50 μ M. Diffuse application of depolarizing drugs to the muscle is known to produce depolarization along the whole fibre¹⁰. Fig. 3 shows that *d*-tubocurarine (7 μ M) also diminished the uptake of labelled carbachol as compared with the control, and a similar effect was found in each of six pairs of muscles which were tested.

lodged in the organs or collected from the circulating blood, so that a greater percentage is capable of reproduction. Also, the smaller number of dead cells and decreased amount of cellular debris in these cell suspensions may decrease the possibility of deleterious interaction with partially damaged cells.

Primary Tissue Phase of *Plasmodium berghei* in Different Experimental Hosts

In a previous communication¹, we reported the finding of pre-erythrocytic tissue schizonts of *P. berghei* in the liver of an experimentally infected young hamster. The forms observed were few in number, involving examination of many hundreds of stained liver sections. The sporozoites used in the former experiments were derived from experimentally infected *Anopheles quadrimaculatus*. In this laboratory vector only small numbers of viable sporozoites reached the salivary glands. The introduction of *Anopheles stephensi* as an experimental vector of *P. berghei*² has greatly facilitated and advanced our work, for in this mosquito species invasion of the salivary glands by very large numbers of sporozoites takes place with regularity after exposure to gametocyte carriers and maintenance at 21° C.

Using techniques of homogenation of infected *A. stephensi* or the trituration of infected salivary glands and midguts, we have been able, by intravenous and intraperitoneal inoculation, to inject large numbers of viable sporozoites, and we have easily found pre-erythrocytic growth forms of *P. berghei* in parenchyma cells of the liver of experimental rodent hosts.

Tissue schizonts have been found in liver sections stained in Giemsa colophonium³ in experimentally infected laboratory-bred tree rats (*Thomomys surdaster*), in hamsters (*Mesocricetus auratus*) in young albino rats^{4,5}, and in white mice.

The inoculation of 500,000–750,000 sporozoites in each of these mammalian hosts of *P. berghei* has produced four to seven tissue schizonts per histological section (1 cm × 0.5 cm in diameter and 4μ in depth). The pre-erythrocytic schizonts show similar morphological features in the different hosts. Growth forms of 18 h, 22 h, 36 h, 48 h, and mature schizonts 51–52 h old were found in the different experimentally infected animals. A search for the early stages of 3–18 h is now in progress.

The regular experimental production of pre-erythrocytic tissue stages of rodent malaria under well-defined laboratory conditions may facilitate research in the chemotherapy and chemoprophylaxis of mammalian plasmodial infections as well as in other fields of malaria research.

A detailed description of the exo-erythrocytic development of *P. berghei* and the techniques involved will be published shortly.

Virus Aetiology for Down's Syndrome (Mongolism)

For many years now, we have been working on the epidemiology of Down's syndrome (mongolism) in the State of Victoria, Australia, and have charted its occurrences during 1942–64. Peaks of incidence, of 2-year duration have been recorded at 5–7 year intervals from 1942 until 1957 and, as a result of this, a further peak of occurrence for this congenital anomaly was forecast for 1962–63. This was the first time ever that such a forecast had been able to be made and, in fact, this eventuated^{1,2}. On the basis of our original findings^{1,2}, we had postulated a hypothesis of an infective virus, of long incubation, affecting mostly, but not exclusively, the ovum of the ageing mother, either directly or through some immunity pattern. Our reasons for this were not only the perception by one of us (A. S.) of a possible clinical relationship between the exposure of the mother to infective hepatitis prior to conception, but also the epidemiological findings that cases of mongol births clustered significantly in time and place, that urban peaks of annual incidence were in every case greater than rural peaks (higher contact rates), and rural peaks followed on

Fig 1 Annual incidence of infective hepatitis in Melbourne, and of mongol births 9 months later for the period 1952 to 1964

one year after urban peaks (suggesting a slow spread of infection out of the high-contact urban areas into the rural areas). Our latest investigations have consisted of an attempt to match the annual occurrence of mongolism in the Melbourne area with the annual occurrence of notifiable infectious diseases during 1952-64, 1952 being the year that infective hepatitis first became notifiable in the State of Victoria. Of all infectious diseases, the incidence of infective hepatitis, charted nine months prior to that of mongolism, has alone shown concordance (Fig. 1); another link in the chain of evidence we had forged relating mongolism to the virus of infective hepatitis, or some process associated with the infection, affecting the ovum prior to, or about the time of, conception. The correlation coefficient between the incidences of mongols, per 100,000 live births, and those of infective hepatitis, per million of population, was 0.81, significant at the level of $P < 0.01$.

We would, in fact, postulate that such a process of virus/human interaction could well be the basis of other genetic anomalies. We have already noted some degree of concordance between peaks of hydrocephaly and mongolism³, even though, in the former, no visible chromosomal abnormality is apparent. A prospective clinical investigation is being put into operation to test the association between infective hepatitis and the occurrence of mongolism; and immunity patterns for this virus, as soon as feasible, will need to be tested on a large group of mothers 'at risk'. Meanwhile, also, examination of the effects of viruses on human cells in culture, and of ovarian tissue in particular, might well open up an undreamed-of prospect of obtaining insight into the production, and thence prevention, of many gene disturbances.

RADIOBIOLOGY

Modification of Radiation 'Cerebral Death' by Hypoxia

PROTECTION from radiation damage by induction of brief periods of hypoxia at the time of irradiation has been demonstrated for a number of intact mammalian tissues¹⁻⁴. There is at present no information available concerning this 'oxygen effect' in the central nervous system. This knowledge is essential if radiotherapy under hypoxic conditions is planned for cerebral tumours. Cerebral damage in the experimental animal following single doses of 2,000-3,000 rads does not normally appear for 6 months or more, so in our attempt to demonstrate this phenomenon we used much higher doses of radiation that give survival times of the order of hours and minutes.

Young adult male Swiss albino mice from a closed colony were used. The animals were anaesthetized with 'Nembutal' (60 mg/kg intraperitoneally) 15 min before irradiation, and irradiated singly in a 'Perspex' box fitted with a gas supply. The box was inserted into a pressed wood block so that the mouse was irradiated head on by a beam of 8-MeV electrons (delivered from the Medical Research Council Linear Accelerator at Hammersmith Hospital) at a dose-rate of 1,600-1,800 krads/min with doses ranging from 50 to 400 krads. Dosimetry was carried out with 'Perspex' disks, and the maximum absorbed dose was recorded at a position level with the brain, 1 cm in from the animal's snout.

Control irradiated mice were supplied with air at a flow rate of 3.5 l./min. Mice irradiated under hypoxic condi-

tions were given pure nitrogen to breathe for 50 sec, with the irradiation given in the last half of this period so that the end of the irradiation coincided with an immediate change back to air. Five seconds or so after irradiation the mice were removed from the chamber and if necessary given positive-pressure artificial respiration with oxygen for 2-3 min or until they breathed spontaneously. One group of animals was given oxygen at 1 atmosphere (A) to breathe for at least a minute before and during irradiation and another set were injected with cysteamine (200 mg/kg, intraperitoneally) 15 min before irradiation in air. All survivals were timed from the end of irradiation.

The figure shows the fitted regression lines of log survival time on dose for air-breathing, air-breathing after cysteamine injection, oxygen-breathing and hypoxic animals. With air-breathing animals, a straight-line response was obtained over a dose range of 50-230 krads. Each point represents results from 6 to 9 animals. The regression lines of the air-breathing and air-breathing-plus-cysteamine animals were identical ($P < 0.001$). The 'oxygen' line, although parallel to the 'air' line, was not identical with it, but showed a shift to the right. The slope of the 'nitrogen' line was not parallel to the 'air' line ($P < 0.001$) and extrapolated below 50 krads crosses the 'air' line at 34 krads. Thus at approximately 50 krads the empirical radiosensitivity of air- and nitrogen-breathing mice would appear to be the same, while the protective effect of nitrogen increases with increasing dose. If one uses the ratio of the regression coefficients from the lines fitted for doses of radiation greater than 50 krads, then the dose modifying factor for nitrogen obtained here is 1.79 (95 per cent confidence limits, 1.64-1.94).

If radiosensitivity is judged by period of survival it is clear that nitrogen breathing has produced a definite protective effect for very high doses of radiation, but the detailed interpretation of the curves is extremely difficult. The apparent lack of effect of nitrogen breathing on radio-sensitivity below 50 krads might be due to the dose approaching the 'plateau' section (10-30 krads) of the curve that Rajewsky⁵ described for survival time-dose on a log log plot. (The survival times for air-breathing animals obtained here with 8-MeV electrons are in good general agreement with Rajewsky's data using 50-kV X-rays at

Fig. 1. Survival times of mice (min) plotted against dose of 8-MeV electrons (krad). ○, Animals breathing air throughout; ●, animals given cysteamine, 200 mg/kg, 15 min before irradiation; □, animals given pure oxygen for at least 1 min before and during irradiation; ●, animals irradiated during last 6 to 12 sec of 50-sec period of breathing nitrogen

10^6 r./min.) An alternative suggestion is that the whole effect is due to the consumption of oxygen by the radiation as demonstrated by Dewey and Boag⁶. They showed that approximately 60,000 rads were required to consume all the oxygen dissolved in an agar gel which was in equilibrium with air at one atmosphere pressure. A mammal breathing air contains much oxygen in its oxyhaemoglobin and oxy-myoglobin and is continually renewing its supplies by breathing. Thus, even with the very high dose rates used here, it is probable that the consumption of oxygen by radiation is of little significance in air-breathing animals. The situation is, however, different for the animals at the end of a period of breathing nitrogen, for not only is the animal's oxygen content reduced but the supply of oxygen is cut off. The consumption of oxygen by the radiation might now be all-important. It would have to be argued that the oxygen tension is not reduced to a level that significantly affects radiosensitivity until 40 to 60 krad have been delivered. Thereafter, increasing doses increasingly render the tissues hypoxic. If this idea is correct it implies that nitrogen breathing, which is known to produce radio-resistance of other tissues, does not under these conditions directly produce radio-resistance in the central nervous system, and that to demonstrate an effect some other additional method of consuming oxygen must operate.

The lack of effect of cysteamine is not surprising in view of the demonstration that the uptake of 35 S-labelled cysteamine in the mouse brain 15 min after injection reached only 1/5 of the amount taken up by the kidneys, liver and gut⁷.

The slight protective effect of oxygen cannot be explained. Protective cerebral vasoconstriction as a defence against oxygen poisoning was suggested in 1921⁸ and there is experimental evidence that breathing O_2 at 1 atm. results in cerebral vasoconstriction⁹ and decreased cerebral blood flow¹⁰. But polarographic studies show increased brain oxygen tension when O_2 at 1 atm. is given^{11,12}. Rectal temperature measurements of anaesthetized mice placed in a stream of O_2 show, in our hands, no greater fall than do those of mice in a stream of N_2 , so a differential cooling effect is not involved.

In conclusion, we can say that nitrogen breathing produces a marked change in radiosensitivity to massive doses of radiation. The mechanism by which this change is brought about is not yet understood, and probably awaits greater knowledge of the fluctuations in available tissue oxygen in the brain.

We thank Mrs. Ann Silvester, Cyclotron Unit, Hammersmith Hospital, for carrying out the irradiations, and for the dosimetry of these experiments. The work was supported by a grant from the British Empire Cancer Campaign for Research.

Acute Radio-sensitivity as a Function of Age in Mice

To understand the 'ageing' effects of the irreparable component of radiation injury, it is essential to accumulate much base-line data on natural chronological ageing. Earlier work¹ was designed to determine radiation sensitivity at different ages, using the fractionated dose method, which allows for biological repair between acute exposures. With this type of exposure, which is primarily a measure of repair from bone marrow injury, radio-resistance remains relatively stable through the first half of adult life and then deteriorates quite rapidly to the end of normal life expectancy². The work described here was designed to investigate variations in sensitivity to single acute X-ray exposures in various age-groups of mice.

Some 2,900 RF-strain virgin female mice of 14 age-groups were used (Table 1). Animals in each age-group were randomly divided into a minimum of 5 and a maximum of 12 acute X-ray exposure groups to bracket the LD_{50} dose. X-ray exposures were made with a 250-kVp X-ray machine with a beryllium window tube under conditions of 30 mamp, 'Thoraeus II' filter, 2.6 mm Cu HVL, 60 cm target-to-specimen distance, and 50 rads/min dose rate.

Table 1. LD_{50} VALUE FOR RF-STRAIN VIRGIN FEMALE MICE AT VARIOUS AGES THROUGHOUT THEIR NORMAL LIFE SPAN

Age (weeks)	No. of mice	LD_{50} (rads)	Standard error
3.6	26	593	14.6
6.0	136	647	18.9
8.0	210	691	14.8
12.8	190	733	13.6
21.4	200	697	15.8
30.0	233	634	20.3
42.8	151	487	18.7
51.4	120	547	36.9
60.0	57	537	16.0
68.6	125	453	5.16
77.1	179	424	22.8
85.7	149	442	17.6
94.3	52	441	12.5
103.6	32	343	18.6

To avoid seasonal effects, LD_{50} evaluations on all 14 age-groups were made within a 60-day period. Standard exposure methods described earlier² for determining LD_{50} values were used. Mice were observed for 30 days after exposure, and lethality data were analysed by standard methods of probit analysis³ to obtain the LD_{50} for each age-group.

Results are presented in Table 1 and Fig. 1. Radio-resistance increased with age from age 3.6 weeks, reaching maximum resistance at 13–17 weeks. At about 18–20 weeks of age, resistance declined throughout the remainder of the life span, reaching a minimum at 104 weeks. There was no apparent period of relative stability in radio-resistance, as was shown earlier¹ with the fractionated technique. Fig. 1 shows increased variability in radio-resistance with increased age after approximately 1 year

Fig. 1. Log plot of variation in radio-sensitivity with age in RF-strain virgin female mice

is reached. This is a characteristic commonly associated with advancing age. An exponential function was a better fit to the data than a linear one. This also is characteristic of many biological parameters.

The difference in response to radiation exposure with age by the acute LD_{50} and the fractionated mean accumulated dose (MAD) methods is not surprising. The sub-lethal fractions given in the fractionated method primarily affect the bone marrow, causing the destruction of one or more stages in the maturation sequence of the erythrocytic series. However, body functions are maintained by the mature radio-resistant erythrocytes in the circulating blood until the bone marrow recovers sufficiently to provide new cell replenishment. Death from a series of widely spaced sub-lethal doses of ionizing radiation is due primarily to repeated damage to the bone marrow to the point at which the red blood cell level is reduced below that necessary to sustain life. Single acute exposures (used in the LD_{50} method), which result in lethality, cause injury to lymphatic tissue and gut, as well as to the bone marrow, and at the time of death in the majority of cases the total erythrocyte count is within the normal range or at least well above a lethal level. In short, death from exposure to ionizing radiation administered by the two different methods is the result of damage to different physiological functions. The comparative results of this and the earlier study¹ suggest a relatively stable repair rate from sub-lethal exposure throughout the first half of the normal life span but waning with age in the last half. However, there appears to be a constantly changing sensitivity in terms of lethality (irreparability) in the critical organs with increasing age. These results are in quite good agreement with those of Crossfill *et al.*⁴ and of Storer⁵. Pertinent literature in this field has been discussed elsewhere^{1,2,4-7}.

Distribution and Effective Half-life of Cobalt-58 in Habrobracon

COBALT isotopes appear in the wastes of reactor installations and are widely used in the control processes of other industries. They have also featured in biology and medicine for nutritional trace-element studies, particularly those involving vitamin B₁₂ (refs. 1 and 2). As an external source of γ -rays for therapeutic and experimental purposes, cobalt-60 has offered many advantages³. However, even though several cobalt isotopes occur in plankton, clams and fish near Bikini⁴, surprisingly few studies of the biological consequences of radiocobalt ingestion have appeared^{5,6}. Even the behaviour of inorganic cobalt has been neglected, despite interesting features of metabolism and transport⁷. Our observations made on a braconid wasp reveal differences between the insect and mammalian pattern of retention and suggest serious consideration of the role of insect vectors in dispersal of fourth period nuclides from contaminated areas.

Young habrobracon (*Bracon hebetor*) females from Whiting Stock No. 33 were fed a single meal from a mixture containing 100 μ c. of carrier-free $^{58}\text{CoSO}_4$ per ml. of

Fig. 1. The average daily radioactivity in c.p.m. of four groups of habrobracon females fed $^{58}\text{CoSO}_4$. Values are corrected for background but not for physical decay. Open circles which represent counts made on three dead wasps demonstrate the slight effect due to physical decay (72 day half-life). No. of wasps used in sub-samples: A, 6; B, 10; C, 9; D, 6.

saturated sugar water. Thus, the average wasp weighing 1.32 mg ingested about 0.5 μ c. of radiocobalt. The radioactivity of each of a sample of 31 wasps was determined daily until death, using a conventional scintillation well counter connected to an integrating decade scaler. The eggs deposited by these females were collected daily and their hatchability determined after 48 h. Another sample of 70 wasps provided groups of 5 individuals which were killed each day for the first nine days plus groups which were killed on days 13, 14, 16, 20 and 25. By counting, the radioactivity was assessed for the whole individual. Then the anterior and posterior parts transected at the petiole were counted separately. Finally, the gut, the fat body with urates and the genital system obtained by dissection were counted. Routinely the average of three counts per specimen was calculated.

Fig. 1 shows the pattern of decline in radioactivity for four sub-samples of wasps followed until death. The average life-span for wasps fed cobalt-58 was 25.6 ± 3.1 days, which compares well with 26.4 ± 2.0 days for controls. To avoid pooling individuals of extremely high and low radioactivity, the 31 females were divided into sub-samples according to their initial counts. Nevertheless in all sub-samples the effective half-life was attained by the third day following a meal containing cobalt-58. During this period most of the radioisotope was abdominal, falling from 98 per cent of the first 2 h through 94 per cent at the end of the first day to 90 per cent on the third day. Even after 20 days, 89 per cent of the cobalt-58 burden was abdominal.

The level of radioactivity of the gut and its contents paralleled that of the abdomen. On the first day, 46 per cent of the abdominal radioactivity was localized in the gut. On the twentieth day the gut still held 43 per cent of the abdominal radioactivity. Much of the remainder was associated with the fat and urate complex. The radioactivity of this tissue climbed from 35 per cent on day 1 to 42 per cent by day 3, and continued to increase in a long sloping plateau to a high of 47 per cent achieved on day 16. After the twentieth day, values fell to a 35 per cent average, understandable on the basis that only live survivors were considered.

Neither ovaries nor eggs became appreciably radioactive, although up to 20 per cent of the abdominal radioactivity during the first three days was associated with the poison apparatus. In contrast, by the third day, ovaries were barely above background, never having contained more than 3 per cent of the abdominal radioactivity. Egg radioactivity follows a simple pattern apparently correlated with the radioactivity of the mother:

Day	1	2	3	4	5	6	7 and later
Counts/mln.	5.52	2.03	2.39	0.73	0.43	0.35	Not above background

Unimpressive egg incorporation differs strikingly from the quantity of phosphorus-32 eliminated via oviposition⁸ and also from the notable third-day peak characteristic of zinc-65 experiments⁹.

Hatchability was low only on the first day (76 per cent). On the second day 98 per cent of the eggs hatched. This and subsequent values were not significantly different from control values.

In mammals, cobalt has been demonstrated to be one of the 'liver-seeking' elements^{10,11}, and on the basis of a rough analogy, localization in the insect fat body might be expected. In addition, the insect tissue has a propensity for storing excess amounts of metabolic products, not only as nutritional reserve but also as storage excretion. Thus histological conditioning towards a persistent radioisotope burden exists. Such an aspect of insect physiology helps to explain an effective half-life several times that in vertebrates where up to 67 per cent of a comparable radiocobalt dose is excreted by the end of the first day¹⁰; but there is also a prolonged association of cobalt with the wasp gut not entirely explained by the Malpighian-tube association. Most of the isotope can be precipitated along with the protein from homogenates of ground wasps. Such preparations on resuspension yield little dialysable cobalt-58, which suggests a firm association of cobalt-58 with tissue components. Furthermore, autoradiographs of ingested nickel-63 demonstrate that transition elements are retained by the cytoplasm of the cells of the mid-gut wall¹². Recently, Wiser and Nelson⁸ have reported a considerably longer time for the elimination of cobalt-60 from crayfish. Here integument adsorption plays an important part in addition to absorption by the gut and hepatopancreas.

Investigations of the bioaccumulation of isotopes of the transition elements appear to be essential for an understanding of potential environmental hazards in an 'atomic age', even though reproductive capacity is not specifically threatened.

BIOLOGY

Experimental Infections of Cattle with *Fasciola hepatica*: a Comparison of Low and High Infection Rates

It has previously been demonstrated, in single infections of cattle with 200–1,300 metacercariae, that an increase in the infection level does not alter the percentage of the infection which becomes patent and that a few of the flukes are inhibited in the damaged parenchyma, particularly in the ventral lobe where a preferential migration of the parasite occurs¹. In subsequent investigations, parasite-free calves were given single infections of

Table 1

Infection level	Percentage take	Mature to immature ratio	Infection length
2,500 m	3	6 to 1	24 and 30 weeks
5,000 m	3.5	1 to 13	30 weeks
15,000 m	0.2	3 to 4	56 weeks
1,300 m	29	20 to 1	23 weeks

2,500, 5,000 and 15,000 metacercariae and killed 24–56 weeks post-infection.

The percentage takes, relative proportions of immature to mature fluke from calves which received 2,500, 5,000 and 15,000 metacercariae, and were killed 24, 30 and 56 weeks post-infection, are shown in Table 1 and compared with previous infections of calves with 1,300 metacercariae, killed at the 23rd week. When the level of infection is increased to 2,500 or more, the numbers of fluke reaching the bile duct is drastically reduced and at the higher levels of infection (5,000 and 15,000), many immature flukes are trapped in the liver parenchyma. That a large percentage of the infections proceeded to the parenchymal migrating stage is confirmed by the greater extent and severity of the cirrhosis present in the 2,500–15,000 infection livers compared with that present in the 1,300 group. The severity and extent of the fibrosis in the bile ducts in the high-level infections are considerably less than that present in infections of 1,300 metacercariae, and this observation, in conjunction with the absence of anaemia in the high-level infections compared with a severe anaemia which developed in the 1,300 infection group in association with the bile duct state infection, confirms that very few of the parasites in the high-level infections reached the bile ducts.

As was previously observed in lower level infections, the distribution of the cirrhosis produced by the migrating fluke was mainly confined to the ventral lobe of the liver. This preferential migration in the ventral lobe of the liver must, in high-level infections, enhance the local reaction and produce inhibition in the later migrating parasites. Many of these inhibited parasites were observed to be trapped within granulomatous tissue and many were dead and in varying stages of disintegration. Within these fibrous lesions considerable bile-ductule proliferation was observed and in some instances fluke eggs were present, indicating that a few parasites achieve patency within the granulomatous mass.

The inhibition phenomenon observed in these high-level infections may explain the rare occurrence of acute fascioliasis in cattle as compared with its high incidence in sheep. With massive infection levels in cattle there is quite considerable destruction of liver tissue, and it may perhaps be important to assess minimum liver tissue requirements in cattle if pathogenesis is to be fully understood.

Haemoglobin in *Ceriodaphnia quadrangula* (O. F. Müller)

In the reports on the presence of haemoglobin in some of the representatives of the Daphniidae^{1–4}, I have found no data concerning haemoglobin in *Ceriodaphnia quadrangula* (O. F. Müller), quite frequently found in ponds and lakes.

In the marginal areas of ponds, large concentrations of this crustacean are quite often observed just below the surface of the water, giving it a red hue. I observed such a phenomenon in the middle of July in the ponds located on the park surrounding Białystok Medical Academy. Hydrochemical data of these ponds are given in Table 1. It is significant that the surface layer of the water con-

Table 1

Temperature °C	21.5
Colour mg/l. Pt	320.0
pH	7.1
O ₂ mg/l (surface)	0.6
Oxidizability mg/l. O ₂	107.0
Cl mg/l.	355.0
Fe mg/l.	—
N (NO ₃) mg/l.	0.3
N (NH ₃) mg/l	0.8
PO ₄ mg/l.	0.1
Ca mg/l.	210.0
Alkalinity mg/l. CaCO ₃	600.5
Total hardness mg/l. CaCO ₃	385.6

tained 0.6 mg O₂/l. whereas at a depth of 0.10 m no oxygen was found.

The population of this crustacean consisted chiefly of mature specimens of the *typica* form. The majority of specimens were 0.713–1.120 mm long. Haemoglobin extraction was performed by the cyanide micromethod^{5,6} after which the absorption curve was determined by means of a Beckman 'DU' spectrophotometer. It was seen from this curve that maximum absorption occurs at a wave-length of 418 mμ (Fig. 1).

For comparison, the maximum absorption of haemoglobin of *Daphnia magna* Straus was determined. It should be mentioned that Hildemann and Keighley⁷, using the same solvent, obtained maximum absorption of *Daphnia magna* haemoglobin at a wave-length of 415 mμ. It has frequently been noted that, although two species of the same genus do not essentially differ morphologically, their haemoglobin has a different maximum absorption. I noted this phenomenon in larvae of the genus *Tendipes*⁸.

In addition to the above investigations, an attempt was made to determine the amount of haemoglobin present in one specimen of *Ceriodaphnia quadrangula*. For the standard curve, crystalline haemoglobin produced by 'Riedl' was used. The four estimates obtained were 1.0, 1.1, 1.1 and 1.2 γ/individual (mean 1.1 γ). The amount of haemoglobin in one specimen varies between 1.0 and 1.2 γ.

Fig. 1. Absorption curve of the haemoglobin of (a) *Ceriodaphnia quadrangula* and (b) *Daphnia magna*

These findings should be considered in relation to the environment, particularly with the amount of oxygen dissolved in it, since cases are known where the amount of haemoglobin increases where there is a small amount of oxygen in the environment^{9,10}.

Red specimens of *Leydigia acanthocercoides* (Fischer) were found in summer, 1963, in the layer just above the bed of Lake Sniardwy. The region round the heart, and the embryos in the spawn, were of a particularly intensive red colour.

These observations suggest that the presence of haemoglobin in invertebrates is usually associated with the occupation of ecological niches containing very little oxygen.

Kinesis

STUDIES on the behaviour of two stored-products beetles, *Carpophilus dimidiatus* F. and *C. hemipterus* L. (Col., Nitidulidae), in humidity gradients prompted a consideration of orientation mechanisms. It was evident that some clarification of the generally accepted classification^{1,2} and its amended forms³⁻⁵ was required, particularly with respect to the definition and interpretation of the various components of kinetic responses.

Kineses, that is variations in random locomotory activity due to changing intensity of stimulus, are classified into ortho- and klino-kineses². The former are defined as variations in either activity, speed or both. The activity of an animal is generally recognized as its frequency of movement. There appears, however, to be some confusion regarding the speed component, which indicates the animal's rate of movement, that is, the distance it covers in unit time. In many studies the time spent motionless by the animal is often included in the time factor of the relationship, distance covered in unit time. Consequently the animal's speed will also involve its frequency of movement (activity) and in this context it may be considered as representing a parameter approaching the 'overall' orthokinetic response. Use of this interpretation of speed will thus invalidate comparison with other species, as it will not be known to what degree the animal's frequency of movement is contributing to the speed component of orthokinesis. The exclusion of resting periods (that is, time spent motionless) from the time factor in the relationship, distance covered per unit time, will therefore indicate the animal's true speed, completely dissociated and independent of activity. An interpretation of this nature provides an objective basis for any comparative studies.

Another point worthy of mention concerns klinokinesis, the concept of which is based on the work of Ulyott⁶, where alteration in rate of change of direction (r.c.d.), later termed angular velocity¹, results in aggregation. It was assumed that changes in angular velocity reflected changes in rate of turning, a parameter which has been the subject of many studies. Alteration in angular velocity, however, may also be brought about by alteration in size of turn alone or by both rate of turning and size of turn. A mathematical analysis of Ulyott's data by Patlak⁷ indicated that it was the size of turn and not

the rate of turning which altered, and hence invalidated the previous assumption that alteration in r.c.d. (angular velocity) reflected a change in rate of turning. It is clear that both rate of turning and size of turn must be taken into account when analysing klinokinesis. Further details are to be published fully elsewhere.

In investigations to determine the existence and nature of kinesis orientation mechanisms, apparatus is invariably employed with little or no regard to the type and nature of the sub-stratum on which the behaviour of the experimental animal is to be observed. Such an item in experimental design may be considered of little importance in affecting behaviour, particularly as Chapman⁸ demonstrated that the surface texture of a heated hardboard plate was unimportant in group formation in nymphs of *Locusta*. It is possible that the animal's behaviour will be distinctly different when observed on various types of substratum, such as perforated zinc, brass wire gauze, steel screening, voile, bolting silk, nylon net and filter paper, all of which have been used in behavioural investigations. Moreover, the position of the apparatus relative to its immediate environment is relevant. Graham and Waterhouse⁹ found that minor inclinations in a 'Perspex' trough resulted in a downward slipping of *Tribolium castaneum* and a significantly uneven distribution. Consequently, studies preliminary to an investigation on kinesis orientation mechanisms in *Carpophilus hemipterus* L. (Col., Nitidulidae) were undertaken in which two of the four parameters of the kinesis response (see above), namely linear velocity (orthokinesis) and rate of turning (klinokinesis), were studied, with respect to two types of substratum.

Untreated adults of *C. hemipterus*, bred at 25° C and 65–70 per cent relative humidity and 7–21 days old, were examined individually under dim diffuse red illumination in uniform humidities of 100 per cent and 0 per cent relative humidities maintained in a round 'Perspex' chamber similar to that used by Gunn and Kennedy¹⁰. The time and route taken by each individual on the cambric (closely woven cotton fabric) false floor and the 'Perspex' roof of the chamber were recorded with a grease pencil on the 'Perspex' roof. Routes taken near and at the sides of these two regions were not taken into consideration, as were those made on the side walls of the chamber, because of the probable limiting influence of the apparatus on the animal's behaviour⁷. A number of tracks were obtained for each individual and these were then transferred to paper where the distance covered and the number of turns made per track were computed with respect to time. At least five individuals of each sex were studied for each humidity and substratum condition. An analysis of variance of linear velocity (cm per sec) and rate of turning (turns per sec) for the different conditions of humidity and substratum was carried out and a summary of the results is given in Table 1, where *H*, *S* and *P* represent humidity, sex and substratum factors respectively.

It can be seen from Table 1 that the type of substratum significantly affects linear velocity, and further analysis showed that a higher linear velocity occurred on cambric (0.51 cm/sec) than on 'Perspex' (0.42 cm/sec).

Table 1. SUMMARY OF RESULTS FOR ANALYSIS OF VARIANCE ON LINEAR VELOCITY (LV) AND RATE OF TURNING (RT) OF *C. hemipterus*

Nature of effect	Source	d.f.		Variance		'F' ratio	
		LV	RT	LV	RT	LV	RT

	Total	244	237				

* Significant at 1 per cent level.

† Significant at 0.1 per cent level.

It is interesting to note that there is a sex reaction difference which was found to be due to the females being faster (0.47 cm/sec) than males (0.44 cm/sec). The effect of humidity on linear velocity was not marked, being significant only at the 10 per cent level, with a tendency for a higher rate of movement at 0 per cent relative humidity (0.47 cm/sec) than at 100 per cent relative humidity (0.44 cm/sec). The rate of turning was only affected by a difference in substratum with further analysis indicating a higher rate of turning on cambric (0.45 turns per sec) than on 'Perspex' (0.36 turns per sec). A factor which may be of importance in interpretation is the dimension in which the behaviour was observed, that is, vertical/horizontal, as it is known that, for example, the activity behaviour of *Porcellio scaber* differs between the horizontal and vertical planes¹¹. The behaviour of *C. hemipterus* individuals was studied in the same horizontal plane when on the two types of substratum, although their primary orientation² was different, as they were moving upside down on the 'Perspex' roof of the chamber whereas on the cambric false floor they were orientated normally. It is believed, however, that the differences in behaviour reported here are due principally to the difference in the type of substratum. Although concerned with only two kinetic orientation parameters, these results lend further support to the view that more consideration should be given to the type of substratum on which the animal's behaviour is to be investigated.

Part of this work was carried out while I was in receipt of a Treasury bursary.

Generation of Nutational Movements

In 1953, Arnal¹ described a characteristic of nutation in *Triticum coleoptiles* which had been hitherto unreported. His observation was that the movement of the coleoptile consisted of the propagation of a wave of bending, of more or less constant amplitude, from the tip of the growing zone towards the base of the organ. He noted that the increasing displacement of the tip from the mean position is caused by the increasing distance of the bend from the tip rather than by an increasing intensity of curvature of a fixed region of the organ. The organ was sometimes observed to possess two or more curvatures of opposite sense at different points along the length of the growing zone.

The purpose of this communication is to report a similar characteristic of the nodding nutations of seedlings of two varieties of *Phaseolus multiflorus* (runner bean). The observations reported here were made by means of time-lapse photographic techniques. The experimental conditions are outlined in Table 1. Bean seedlings at the 1st–2nd internode stage photographed under these conditions exhibited waves of bending as shown in Fig. 1. This shows silhouettes of bean seedlings at 15-min intervals, drawn from the time-lapse photographs. The numbered

brackets trace the course of each successive bend as it passes down from the tip. The positions of the bending regions were determined by careful comparison with the preceding frame. The rate of propagation of the bend was in all cases in the region of 2 cm/h. A similar pattern of movements has also been observed by me in horizontally growing, etiolated potato stems shown in a commercially available film *Plant and Light*².

Fig. 1. Silhouettes of 'Prizewinner' beans at 15-min intervals. The numbered brackets trace the course of each bend.

From the rate of travel of the waves of bending, it is likely that the nutational oscillations are transmitted through some mechanism similar to the auxin transport system. The theory put forward by Arnal¹, which suggested that the nutational oscillation was a modulation of auxin production at the tip, has been disproved by Joerrens³, who observed nutation to occur in decapitated *Triticum* coleoptiles supplied with auxin-lanolin paste. It is possible that such patterns of movement could be generated by a modulation of the volume of polar transport, with the oscillations of opposite sides of the organ 180° out of phase. These observations are also compatible with Gradmann's⁴ theory which describes nutation as geotropic 'hunting' of the growing organ for the vertical position. This interpretation is doubtful in the case of the two varieties of *Phaseolus* examined by me which frequently do not 'overshoot' the vertical position, but 'nod' to one side only. Moreover, in the case of the orthogeotropic oscillations described by Bennet-Clark and Ball⁵ in *Aegopodium podagraria* rhizomes, the oscillations induced by a change from the normal orientation rapidly damp out whereas the oscillations of nutating plants continue throughout the growing period.

Thermal Contraction in Twigs

CHANGES in linear dimensions or volume of plant parts often are assumed to represent changes in growth. However, plants routinely undergo reversible changes in size resulting from hydration and thermal effects. Sometimes such reversible changes are not very large and do not complicate growth studies. At other times, however, they may actually exceed changes resulting from accretion through meristematic activity. For this reason more attention should be given to distinguish between total dimensional changes of plants and those caused by tissue growth alone. Hydration effects on plants are considered elsewhere^{1,2}. The present discussion deals primarily with thermal influences on dimensional changes in woody plants.

As early as 1906 Weigand³ noted that woody plants shrank considerably after exposure to cold. Daubenmire and Deters⁴ demonstrated that unseasonal drops in temperature not only decreased cambial activity but also caused considerable stem contraction. When temperatures dropped abruptly in the winter, contraction of tree stems occurred rapidly and often amounted to much more than the amount of cambial growth the previous summer. Such shrinkage was primarily a function of species and stem size⁵. Byram and Doolittle⁶ noted in North Carolina that, shortly after a cold spell beginning on January 19, the outer layer of living tissue of *Pinus echinata* stems contracted about 10 times as much as the mean daily shrinkage that occurred during the period of rapid spring growth. During the winter Small and Monk⁷ found highly significant correlations of average radial change of *Fraxinus* stems and air temperature. The highest temperatures usually occurred at noon, and major radial increases occurred at the same time. These experiments have been extended to compare the influence of low temperatures on twig diameters of both gymnosperms and angiosperms.

In the first experiment 10 twigs, each 6 in. long and 0.6–0.9 in. in diameter, were collected from each of 6 species including *Pinus sylvestris* L., *P. strobus* L., *P. ponderosa* Laws., *Acer platanoides* L., *Betula papyrifera* Marsh., and *Quercus robur* L. To minimize loss of water the cut ends of the twigs were coated with shellac and all twigs placed in sealed polythene bags. Small plastic disks had been glued to opposite sides of each twig to identify the points of measurement. A micrometer gauge with fine anvils and very light pressure override was used to determine twig diameters to 0.001 in. Small sections of bark were removed from each twig for determinations of thickness. After 2 days at 20° C the diameters of each twig were determined and the specimens were then transferred to a cold room at –20° C. Diameters were remeasured daily for three successive days and the twigs were then returned to a room for thawing at 20° C and final measurement.

After transfer from 20° C to –20° C stem contraction in all species, except *Pinus sylvestris*, was most marked after 24 h (Table 1). Thereafter further contraction was small. Retransfer to 20° C caused expansion, and in most cases diameters after thawing exceeded the original diameters. This anomaly probably resulted from some experimental error associated with loss of the plastic disks during thawing. Large differences in thermal contraction occurred among species. Shrinkage varied from less than 1 per cent of the diameter in *Pinus strobus* twigs to near 5 per cent in *Acer platanoides*. Twigs of angiosperms as a group contracted much more than those of gymnosperms. This was consistent with data of Winget and Kozlowski⁸, who noted a much lower winter contraction of stems of *Tsuga canadensis* than those of several species of angiosperms. In the work recorded here, thickness of bark did not

Table 1. EFFECT OF TEMPERATURE CHANGE ON TWIG DIAMETERS. MEASUREMENTS WERE TAKEN AFTER 24 H AT EACH INDICATED TEMPERATURE

Species	Mean diameter (0.001 in.)	Mean bark thickness		Diameter change (as % of original diameter at 20° C)				
		(0.001 in.)	(% of diameter)	-20° C	-20° C	-20° C	3° C	20° C
<i>Pinus sylvestris</i>	780	47	12.0	-0.41	-0.87	-0.93	0.55	0.90
<i>Pinus strobus</i>	486	56	25.7	-0.23	-0.14	-0.52	-0.14	0.01
<i>Pinus ponderosa</i>	680	97	28.5	-1.26	-1.25	-1.35	0.52	0.44
<i>Quercus robur</i>	794	93	23.4	-2.50	-2.85	-2.88	-0.15	0.68
<i>Acer platanoides</i>	708	48	13.5	-3.90	-4.58	-4.49	-1.38	-1.30
<i>Betula papyrifera</i>	745	34	9.1	-2.31	-2.60	-2.55	0.72	1.29

correlate well with thermal contraction. Bark was about as thick in *Pinus ponderosa* as in *Quercus robur*, but twigs of the latter species shrank much more. *Pinus sylvestris* had the thinnest bark of the three pines examined; but its twigs contracted more than those of *Pinus strobus* and less than those of *Pinus ponderosa* (Table 1).

In another experiment 10 branches, each 8 in. long and 0.7-1.0 in. in diameter, were collected from each of three species including *Quercus robur*, *Acer platanoides*, and *Fagus sylvatica*. The bark was then removed from five

of the specimens of each species. All specimens were coated with shellac to minimize loss of water, and plastic disks were positioned at opposite sides of each specimen to identify points of diameter measurement. Initial diameters were recorded in a room at 20° C. The specimens were then placed in polythene bags and transferred to a cold room at -4° C for remeasurement. The temperature was then decreased to -20° C and diameters were measured twice at 24-h intervals before transfer of the specimens to a room at 20° C. Then the twigs were stored for 14 days at -20° C and afterwards thawed at 20° C. Diameters of specimens with and without bark were measured in these warm and cold environments. After transfer from a warm to a cold environment all specimens with bark shrank much more than those without bark (Fig. 1). Twigs with bark often contracted several times as much as those without bark, even though bark thickness was much less than wood thickness. This emphasized that most of the contraction occurred in the bark. Some contraction of wood alone occurred, but this was usually a small amount.

To determine how much the bark alone would contract and expand in warm and cold environments, small samples of bark, each 2 in. × 1 in. × 0.5 in., of *Quercus robur* were used. Points for measurement were marked on each sample prior to coating them with shellac to minimize loss of water by evaporation. To test the efficiency of the seal the specimens were kept at 20° C for 24 h and then transferred to a cold room at -20° C. Thickness measurements were made at 20° C immediately after sealing, 24 h later at 20° C, and after 24 h at -20° C. The specimens were then thawed at 20° C for remeasurement. They were measured again 48 h later at 20° C, and once more 6 days later at 20° C, when they appeared to have lost considerable moisture. They were then transferred to -20° C for 48 h and remeasured. Five specimens of each species were then placed in polythene bags and 5 were left exposed. Final measurements were made after an additional 48 h at 20° C.

Marked shrinkage of the pieces of bark occurred during the first 24 h at 20° C because of water loss (Fig. 2), but

Fig. 1. Thermal changes in diameters of twigs of three species of angiosperms. Diameter changes are given as percentages of original diameters at 20° C. Black, without bark; white, with bark.

Fig. 2. Thermal and desiccation changes in isolated bark samples after exposure to warm and cold temperatures. Much of the contraction was caused by desiccation.

shrinkage was accelerated in the cold room at -20°C . On thawing the specimens expanded to the thickness at which freezing began, but shrinkage continued as water thereafter was lost at 20°C . The amount of contraction in the final freezing was negligible in comparison to that which occurred earlier, and recovery was slight. No recovery was observed in the five exposed specimens, and slight but not complete recovery occurred in the specimens in the polythene bags. This indicated that loss of water was occurring from the exposed specimens causing further contraction rather than expansion.

Occurrence of Gnetalean Pollen Grains in the Katrol Formation (Upper Jurassic) of Kutch, India

WHILE carrying out palynological investigations of the samples from the Katrol formation (Upper Jurassic) of Kutch, pollen grains with close morphological affinity to *Ephedra* and *Welwitschia* pollen grains were observed along with plenty of Upper Jurassic spore pollen types and microplanktons (*Hystriosphæridium*, *Baltisphaeridium*, *Michrystidium*).

The samples consisted of black carbonaceous gypsiferous shales. These were digested in hydrofluoric acid for 24 h and the residue treated for 12 h with nitric acid and potassium hydroxide. The lighter fraction was separated by means of a heavy liquid of specific gravity 2.3 (a mixture of potassium, cadmium and zinc iodides). Permanent slides were prepared in glycerine jelly and sealed with vinyl acetate solution.

Ephedroid grains (Figs. 1-3) are perprolate, $48-106\mu \times 22-42\mu$ in size, ends rounded, exine thin with 14-24 ridges. The ridges were $2-3\mu$ thick, narrowing and converging towards the poles, $1-2\mu$ apart, alternating with furrows. Hyaline lines are not visible in any of the grains. Exine is characteristically Gnetalean. The morphological characters of the sporomorphs show close similarities to the pollen grains of *Ephedra*.

The sporomorphs with a morphological similarity to *Welwitschia* (Figs. 4 and 5) are perprolate, monocolpate colpa extending from one end to the other of the larger axis, exine scabrate, thick, marked by thin ridges comparatively close-spaced, size $67-50\mu \times 28-20\mu$.

The order Gnetales has a poor macrofossil record. In recent years, however, considerable evidence has been obtained on the occurrence of the group in the geological past throughout the world, based on pollen finds. The earliest record so far of pollen grains related to Gnetales comes from the Middle Permian of Oklahoma. Wilson¹ designated them as *Ephedripites* sp. and *Vittatina* sp., and considered them to be the ancestral forms of *Ephedra* and *Welwitschia*.

From Indian sediments, Bharadwaj² reported the occurrence of Gnetalean pollen in the Raniganj stage (Upper Permian), East Raniganj Coalfield; Ghosh *et al.*³ recorded *Ephedra*-type pollen from the Dharmasala beds (Lower Miocene to Oligocene) of Kangra District, Punjab;

Figs. 1-5

Wodehouse⁴ recorded pollen from the Pleistocene of Kashmir.

That the distribution of *Ephedra* during the Jurassic period extended as far as Kutch ($22^{\circ}45' \text{N}$. and 24°N . Lat. and $68^{\circ}15' \text{E}$. and 71°E . Long.) is interesting, for its present-day distribution is restricted to Kashmir and north-west India. It may be mentioned that *Ephedra*, a xeric plant, is to be found in dry regions, warm areas and also at high altitudes in the mountains.

Welwitschia, a monotypic genus, is restricted only to certain regions of south-east Africa, where extreme desert conditions prevail.

Increase during Winter in Capacity for Root Regeneration in Detached Shoots of Fruit-tree Rootstocks

THE ability of plants to form adventitious roots in detached portions of shoots has provided the horticulturist with a ready method of multiplying plants vegetatively by cuttings.

Fluctuations in the regenerative capacity of shoots throughout the year are well known, and plants which are considered difficult to propagate are often only rooted from cuttings during a limited period, usually when the shoot is in active growth^{1,2}. Hardwood cuttings, taken during the dormant season, are usually preferred wherever possible, however, mainly because elaborate control of the rooting environment is not necessary to ensure their survival.

The traditional time to plant hardwood cuttings in England is in the autumn³, when soil conditions are most suitable; but recent experiments with fruit tree rootstocks have shown that the capacity of the shoot to regenerate roots is at a low level at that time, but increases to a high level prior to regrowth the following spring (Fig. 1a, b, c). Hardwood cuttings of 'Crab C' and 'M.26' apple rootstocks and 'Myrobalan B' plum rootstock showed an increase in the number of rooted cuttings, and usually in the mean roots per cutting and mean root weight during winter. So far it has not been possible to observe this effect clearly when planting cuttings directly into the soil, as is the usual custom, because the environment changes markedly throughout the winter; but the development of a rooting environment for hardwood cuttings^{4,5}, in which they are subjected to a standard period of controlled temperature, has now overcome this difficulty.

Preliminary experiments involving low-temperature storage and bud removal suggest that this increase in

rooting is associated with the decreasing level of dormancy in the buds following winter chilling, a factor shown by other workers to be important^{6,7}.

VETERINARY SCIENCE

Carcinogenic Activity of Bracken

THE bracken plant (*Pteridium aquilinum*) is known to contain radiomimetic activity. Ingestion by cattle of the whole plant, or of extracts, produces a syndrome in which there is pancytoid bone-marrow damage, pyrexia, and often gut-lining damage and ulceration¹; also typical are the widespread petechial haemorrhages².

Rosenberger³ reported the presence of haematuria in cattle fed bracken over long periods, and that changes of a polypous-tumorous nature occurred in the bladder mucosa. Georgiev⁴ obtained an extract from the urine of cattle fed hay from haematuria districts, which, when introduced into the urinary bladders of dogs, produced changes similar to a haemangioma. Applications of the same extract to the skin of white mice produced papilloma-type excrescences. Since many radiomimetic chemicals have a delayed carcinogenic effect it was felt worthwhile to test the possible carcinogenic activity of bracken directly.

Bracken frond was collected in June 1964 and oven-dried at 40° C for 48 h, after an initial period of 60 min in a tumbler dryer at 50° C, which removed most of the moisture. This material was then milled, mixed with milled Levers No. 4 rat diet in the proportion diet 66 per cent and bracken 34 per cent by weight, made into pellets and dried to avoid mould growth.

This diet was fed to 7-week-old, Glaxo strain, hooded Lister non-inbred rats, twenty of each sex (average male weight 125 g, female 110 g). It was found impossible to estimate the amount consumed due to the wastage incurred, but no other food was offered and the diet fed *ad lib.* for 64 days, from August 14 to November 11, 1964, inclusively and from January 8 to 18, 1965; the rats were then returned to the normal diet.

Since bracken also has a thiaminase enzyme quite distinct from the 'cattle factor'⁵, it was necessary to provide extra-dietary B₁. This was given by subcutaneous injection of B₁ (3 mg in 0.2 ml. physiological saline/rat) in the flank, while the animals were under light ether anaesthesia, on September 30, October 14 and October 30, 1964, respectively. Forty control animals of the same age and weight receiving the normal rat diet were given the same treatment; all these animals are alive and healthy.

To date (July 26, 1965) all 20 male rats and 14 of the females from the group fed the bracken diet have died or have been killed in poor condition, the first 3 males dying 29 weeks after the start of the experiment.

Post-mortem examination revealed the presence of numerous multiple tumours protruding into the lumen of the intestine; these occur throughout the small intestine, but predominantly in the ileal region. While most are of the order of 5–18 mm in diameter (Fig. 1), ten of the

Fig. 1. Percentage rooting of 24-in. basal hardwood cuttings collected from randomized portions of hedges on the occasions shown and, after treatment with a root-promoting substance (γ -(3 indolyl)-butyric acid) rooted for 28 days in a peat-sand compost at 65° F minimum bottom heat in 1963-64 and 70° F minimum bottom heat in 1964-65. LF is the mean date between the beginning and end of leaf-fall, and B the inclusion of swelling buds on the cutting. Each value is the mean of 6 replicates of 10 cuttings, trends being significant, $P < 0.001$. a, 'Crab C'; b, 'M.26'; c, 'Myrobalan B'.

Fig. 1. Ileum opened longitudinally, showing adenocarcinoma

animals had developed a very large tumour 2-4 cm in diameter, as well as the other smaller widespread tumours. Frequently the larger tumours protruded through the muscle wall of the intestine, often with adhesions to the surrounding tissues and organs. Most of the animals scoured badly and some had intussusceptions caused by one of the tumours; in other cases a diverticulum or a ballooning of the intestine was found. The only animal not conforming to this general pattern was a female which developed a mammary tumour. One tumour has been found so far in four white rats fed the diet, but of 50 Swiss white mice fed, none has yet shown any effects.

Histological examination of these tumours has revealed proliferation of the epithelial layer of the intestine. Numerous mitoses can be seen in the columnar cells and, while the original structure of the villi is visible, the cells are more closely packed and several layers thick. Dr. R. Schoental of the Medical Research Council Toxicology Research Unit, Carshalton, kindly examined both animals and sections prepared from the tumours, and confirmed the presence of malignant adenocarcinoma of the mucosa.

Intestinal tumours in rodents are rare, although Schoental^{5,6} reports induction by polycyclic aromatic hydrocarbons and irradiation. Of interest is a recent private communication from Mr. W. H. Parker and Mr. C. T. McCrea (Veterinary Investigation Centre, Thirsk, Yorkshire) noting that in the course of a survey on the causes of death in sheep on the North Yorkshire Moors⁷, a number of older animals from bracken-infested areas were found to have died of the same type of tumour.

Work is now in progress to find the causative agent by trials with bracken extracts; the residue of fibrous material after extraction is also under test, to eliminate the possibility of an irritant action.

We thank Dr. Schoental and other members of the Toxicology Unit for their help and advice, Mr. I. S. Farr for the photography and Mrs. N. Mason for histological

preparations. One of us (J. M.) was supported by a grant from the Department of Scientific and Industrial Research.

MICROBIOLOGY

Accumulation of Keto-acids in Tissues during Diphtheria Intoxication

AN earlier investigation¹ revealed that during citrate dissimilation by non-proliferating suspensions of *Klebsiella aerogenes*, diphtheria toxin caused increased accumulation of pyruvic and α -ketoglutaric acid. This observation suggested that diphtheria toxin acts by diminishing the utilization of keto-acids in tissues. It was, therefore, decided to investigate the effect of diphtheria toxin on the keto-acid content of blood and tissues in guinea-pigs.

A solution of Pope's purified diphtheria toxin was prepared by dissolving the toxin contained in a vial (kindly supplied by Dr. C. G. Pope) in 5 ml. distilled water. The solution contained 4,200 Lf/ml. Different doses of purified toxin were injected subcutaneously into guinea-pigs. After 18-24 h the animals were killed by stunning and bleeding from carotid arteries. Various tissues, including heart, kidney, adrenals, spleen and liver, were immediately removed. Tissue slices weighing approximately 0.5-1 g (or the entire organ when it weighed less than 0.5 g) were used in keto-acid estimations. 5 ml. blood was collected by cardiac puncture, immediately before killing the animals, for estimating keto-acids in blood. The tissue slices were homogenized in trichloroacetic acid, and α -ketoglutaric and pyruvic acids were determined by the method of Friedemann and Haugen². Similar techniques were used in normal guinea-pigs.

The results (Table 1) show that in diphtheria intoxication there is an increase in keto-acids in guinea-pig tissues. This is observed in liver, heart, spleen, kidney and adrenals, but it is fairly marked in spleen and adrenals. There is little or no increase in blood keto-acids.

It still remains to be seen as to how far this observation, that is the diminished utilization of keto-acids in diphtheria intoxication, can be interlinked with another observation reported earlier³ that diphtheria toxin inhibited acetylcholine synthesis in rat brain slices and this was probably due to a diminution in the content of the parent substrates, acetyl CoA and choline, which are necessary for acetyl

VIROLOGY

Inhibition of Influenza Virus Haemagglutination by Polymerized Orosomucoid

THE inhibition of haemagglutination by indicator influenza virus using mucoprotein inhibitors is a well-established observation¹. It has been proposed that for a molecule to inhibit viral haemagglutination it must not only contain sialic acid as an end-group susceptible to neuraminidase, but also be of 'minimum size'². Orosomucoid³, a serum glycoprotein containing 11 per cent of neuraminidase-susceptible sialic acid, however, does not inhibit viral haemagglutination⁴. It has been suggested that orosomucoid may fail as an inhibitor because its molecular weight of 41,000 is too low². We have found that incubation of this glycoprotein at 80° C caused it to polymerize in solution and to become an active inhibitor of certain strains of influenza virus⁵. Further observations on this phenomenon are reported here.

Orosomucoid was isolated from the urine of adult patients with the nephrotic syndrome, by means of chromatography on DEAE cellulose⁶. The preparation had been shown to be of high purity by electrophoretic, ultracentrifugal and immunochemical analysis⁶. Solutions of orosomucoid were prepared, 1 per cent in 0.9 per cent saline, and subjected to incubation for 1 h at the following temperatures: 37°, 56°, 66° and 80° C. A control solution was maintained at a room temperature of 20° C. Each of these solutions were then tested against indicator influenza virus as detailed here.

A further solution of orosomucoid in saline was subjected to analysis in the analytical ultracentrifuge before and after heating at 80° C for 1 h. In addition another solution of orosomucoid in 0.9 per cent saline was prepared of 1.6 per cent concentration and incubated at 37° C for 24 h. After specific time intervals, samples of the solution were withdrawn for testing against influenza virus *A/ENG/1/63*. These samples were then stored at 4° C for one month and then, with normal laboratory handling, re-tested against the same strain of virus. The control solution in this series was a solution of identical concentration in saline and stored at 4° C.

Indicator viruses were prepared as follows:

Influenza *A/PR8*, *A₁/ENG/55*, *A₂/ENG/1/63* and an *A₂* isolate of 1957 were diluted 1 in 5 in borate-citrate buffer (Clarke and Lubs's borate buffer⁷ pH 8.5, 1 vol., 0.2 per cent sodium citrate in 0.9 per cent saline, 9 vol.)⁸ and heated at 56° C for 30 min. Influenza *B* Lee strain was heated in undiluted allantoic fluid at 56° C for 30 min. Sufficient material was produced to carry out all titrations of orosomucoid at one time, except where samples of orosomucoid were re-tested one month later, when fresh indicator viruses were prepared under identical conditions from the original seed viruses. Eight haemagglutinating doses of indicator viruses were used with the exception of the Lee strain where four were used. Serial two-fold dilutions of orosomucoid were made from 1:100 to 1:51,200 for the heated preparations and from neat to 1:512 for the untreated controls. The cell suspension was 1 per cent fowl red blood cells. The unit volume was 0.25 ml., and the diluent was veronal buffered saline pH 7.2.

Table 1. INHIBITION OF INFLUENZA VIRUS BY HEATED OROSOMUCOID (Orosomucoid 1 per cent in 0.9 per cent saline)

Table 2. INHIBITION OF INFLUENZA VIRUS *A₂/ENG/1/63* BY OROSOMUCOID INCUBATED AT 37° C (Orosomucoid 1.6 per cent in 0.9 per cent saline)

Incubation period (h)	Haemagglutination inhibition titres
Control	160
1	320
3-25	1,280
5-25	>1,280
6-5	2,560
10-5	5,120
24	>5,120 <10,240

A haemagglutination dose of 8 units was used.

The results of ultracentrifugation are given in Fig. 1 and the inhibition investigations in Tables 1 and 2.

The interesting feature of the polymerization of orosomucoid on incubation at 80° C is the extent and degree of specificity of the reaction. Of the original monomer some 72 per cent had polymerized to a polymer of sedimentation constant 20.1S. Although γ -globulins are known to polymerize on incubating, the extent of polymerization is usually much smaller and of a much less specific nature⁹. These results were confirmed on two preparations of orosomucoid from individual patients. The results of inhibition (Table 1) confirmed that native unheated orosomucoid is not a significant inhibitor of haemagglutination by influenza virus. However, the heated material strongly inhibited haemagglutination by the strains *A/PR8* and *A₂/ENG/1/63* but not *A₂/57* or *A/55*. The possibility of orosomucoid becoming active against influenza virus at physiological temperatures is evident from Table 2, showing the results of incubation at 37° C.

Independent work by Morawiecki and Lisowska¹⁰ has also demonstrated inhibition of haemagglutination by influenza *B* virus (Lee strain), using orosomucoid polymerized by heating at 50° C for 24 h a 5 per cent solution in phosphate-acetate buffer pH 4.3 containing 1.3 per cent acetaldehyde. However, these workers stated that their heated 'control' solution, in acid buffer without acetaldehyde, gave polymers so unstable that the inhibiting effect against the Lee strain disappeared after 2-3 h. All the original incubated solutions described here retained their inhibition titre for several days, and it was specifically recorded that the solutions incubated at 37° C did not lose their activity against virus strain *A₂/ENG/1/63* when stored for 4 weeks at 4° C.

Morawiecki and Lisowska¹⁰ recorded an increase of 600-fold inhibition using their system of polymerization against their Lee strain of influenza virus. The present

Fig. 1. The ultracentrifugation of orosomucoid (1.6 per cent in 0.9 per cent saline) before and after incubation at 80° C for 1 h. The figures below each photograph give the time of spinning in minutes

work would suggest that the net inhibition increase varies with the strain of virus. Of the strains listed here, the inhibition against the PR8 strain was increased by a factor of 1,600, against the $A_2/ENG/1/63$ by 200, and against the Lee by 160. However, no increase was recorded for the $A_2/57$ and $A/55$ strains.

Electron microscopic observations on the fraction heated at 80° C and negative stained with potassium borotungstate regularly recorded structures of diffusely fibrous appearance which were never present in the unheated material.

The observations recorded here must add new significance to the 'criteria of viral inhibition' as developed earlier by Gottschalk². However, it is still conceivable that polymerization is not the cause of this new biological property of orosomucoid, as other physical or chemical changes as yet undetected may ultimately prove responsible.

We thank Dr. D. R. Stanworth of the University of Birmingham for his assistance in the ultracentrifuge investigations.

CYTOLOGY

Demonstration of the Spiral Structure of Human Chromosomes

CHROMOSOMES have generally been regarded as consisting of coiled chromonemata. Although a number of cytological observations on the structure of chromosomes in plant germ cells have been conducted, as well as many studies on the fine structure of animal chromosomes at the molecular level, structural relations of chromonema and its molecular components are still poorly defined^{1,2}. Since the Denver Conference of Human Chromosomes Study Group, a number of morphological investigations have been carried out on the identification of each chromosome to establish the standard normal human karyotype, particularly with respect to the sites and relative frequencies of secondary constrictions³⁻⁵. There is general agreement regarding the normal karyotype; however, little or no morphological evidence has been presented to confirm the spiral structure of human somatic chromosomes. As an innovation to the technique for chromosome preparation, the following method has been developed which clearly demonstrates somatic coils through the partial dissociation of human chromosomes.

Peripheral blood leucocytes, harvested and maintained by standard methods, were used. Three-day cultures were treated with colchicine (final concentration of 0.06 µg/ml.) for 1 h at 37° C and the cells were suspended by shaking. The leucocytes were then concentrated by centrifugation in 15-ml. tubes and the supernate was discarded. The partial dissociation of the chromosomes was effected by treatment with 2-3 ml. of a 4:2:1 mixture of equimolar solutions of KCl, NaNO₃ and CH₃COONa. Originally,

this solution was developed by Matsuura *et al.*⁶ to obtain clear demonstrations of chromosome structure of the pollen mother cells of *Trillium*. Their procedure utilized 0.33 molar concentrations of these salts for 1.5-2.0 min. The optimal chromosomal dissociation of human leucocytes was obtained only after testing many combinations and ranges of the three parameters: concentration (range from 0.041 to 0.33 moles), time (20-150 min), and temperature (4°-50° C). The application of 0.055 mole of the three salts in the 4:2:1 ratio already described for 90 min at room temperature (21°-22° C) appeared to yield the best results, showing clear spiral figures without serious distortions of the chromosomal configuration (Fig. 1).

The salt concentration was found to be critical. Higher concentrations gave more severe uncoiling but did not give a clear figure. Lower concentrations gave slender, well-defined chromosomes but no visible spiralization. High temperature (37°-50° C) produced an indistinct chromosomal outline.

At the end of this treatment, 5 or 6 ml. of freshly prepared cold fixative solution (3 parts absolute methanol: 1 part glacial acetic acid) were added to this cell suspension, followed by a very gentle mixing with a pipette. About 30 min later, the fixative was exchanged with a fresh solution at least three times. One or two drops of cell suspension containing an adequate cell number were then dropped on a clean slide and allowed to dry. The preparations were scanned at this stage using phase contrast microscopy. After 1 or 2 h, slides were lightly stained with Giemsa, avoiding the loss of details by over-staining. Slides were then washed with running water for a few seconds and allowed to stand at room temperature for complete dehydration. After slides had been dipped in xylene for about 5 min, the coverslips were mounted with 'Permount'. The chromosomes were photographed using bright-field microscopy (Fig. 1) for an analysis of the number of gyres and the appearance of the secondary constrictions (Fig. 2).

Fig. 1. Metaphase from a cultured blood cell of a male. The spiral structure (somatic coil) is clearly demonstrated.

Fig. 2. Chromosome Nos. 1, 9, 11 and 16 from the cell in Fig. 1 at higher magnification. Arrows indicate the loci at which secondary constrictions appear. Note the configuration of the chromonemata.

In addition to confirming the hypothetical helical configuration of human chromosomes, this study demonstrated that secondary constrictions are less tightly coiled regions of the chromonemata. Moreover, this technique offers the possibility of a more quantitative analysis of chromosomes at the chromonema level. If a reproducible gyre number is established, coil counts may become a more accurate method of determining arm ratios. The analysis of chromosome breaks or translocations, induced by treatment with chemicals or ionizing radiation, may be described more accurately with partial dissociation of the chromosomes. Quantitative studies regarding the number of helices and the measurement of the length and diameter of the coils are now in progress and will be published elsewhere.

This work was aided by grant GB-15 from the U.S. National Science Foundation, administered by Dr. Donald E. Rounds. I thank him for his advice.

This communication is dedicated to Prof. Sajiro Makino, Zoological Institute, Hokkaido University, Sapporo, Japan, in honour of his sixtieth birthday on June 21, 1966.

GENETICS

Chimerical Nature of the Entire-leaf Variant in the Potato Variety 'Majestic'

THE docken, or entire-leaf variation (Fig. 1), like several other variations for leaf shape in potatoes, has not been shown previously to be a chimera. Leaf shape in potatoes is largely determined by the constitution of L_2 (ref. 1), and the two standard methods of investigating potato chimeras, breeding behaviour and eye-excision, give information on L_2 in the variant and not on L_1 . It is thus not possible by these two methods to show that L_1 in a variant is unchanged. Information of L_1 may, however, be obtained by X-ray treatment².

Crossing 'Majestic' docken-leaf with 'Ulster Prince' resulted in a family with a segregation of 23 seedlings with entire leaves: 17 seedlings with compound, pinnate leaves

(the control cross of normal 'Majestic' with 'Ulster Prince' gave 53 seedlings with a compound, pinnate leaves and none with entire leaves).

Eye-excision experiments with docken-leaf tubers produced only plants with entire leaves, no normal 'Majestic' plants being obtained. Root buds, produced by the method of Howard³, also resulted only in plants with entire leaves. It thus seems that docken-leaf in 'Majestic' results from a mutation for entire leaves in the L_2 layer and that the L_2 layer also now has the same constitution as that of L_1 ; a similar replacement of L_2 by L_1 cells has been observed in triploid-hexaploid potato chimeras⁴.

Five apical (rose) ends of tubers of docken-leaf 'Majestic' were given an X-ray dosage of 3,500 r. Four of them produced plants and one of the four had a mixture of normal and docken-leaf shoots. The production of the shoots with normal leaves was presumably because in the docken-leaf variant L_1 is still normal, unchanged 'Majestic'. The frequency (about 12.5 per cent) of shoots with all layers with the constitution of L_1 in the variant is similar to that of full 'Red King' from normal 'Red King' and of white from 'Bante' sports after X-ray treatment⁵.

The finding that the docken-leaf sport is a chimera in which L_1 is still normal 'Majestic' suggests that certain other variants, such as wildings, feathery wildings and bolters, which do not appear to be chimeras from the results of eye-excision experiments, may be chimeras in which L_2 and L_3 have the mutated character but in which L_1 is still unchanged.

Estimation of the Frequency of Functioning Gametes in Monosomics

WE regret that the estimates of p and q of the functioning male gametes with n and $(n-1)$ chromosomes respectively given in our recent communication¹ are not consistent. The correct estimates should be as follows.

On applying the maximum likelihood method, the estimate of p may be obtained by taking the positive root of the quadratic equation:

$$p^2[N(p' - q')] + p[q'(a_1 + a_2) - p'(N + a_1)] + a_1p' = 0 \quad (1)$$

and the variance of the estimate will be:

$$V_p = \frac{p^2q^2(p'q + pq')^2}{(p'q + pq')^2(a_1q^2 + a_2p^2) + a_2p^2q^2(q' - p')^2} \quad (2)$$

where a_1 , a_2 and a_3 ($a_1 + a_2 + a_3 = N$) are the observed frequencies of disomic, monosomic and nullisomic respectively and p' and q' ($p' + q' = 1$) are the relative frequencies of the functioning female gametes with n and $(n-1)$ chromosomes respectively.

The square root of V_p will give the standard error (S.E.) of the estimate.

It can be shown that:

$$\text{when } p = q' = \frac{1}{2}$$

$$p = \frac{2a_1}{N} \text{ and } q = \frac{2a_3}{N}$$

and the variance of the estimate will be reduced to $\frac{2pq}{N}$.

By using (1) in our numerical example¹, we obtain:

$$-59.28p + 12.08p + 3.12 = 0$$

giving $p = 0.3529$ and $q = 1 - p = 0.6471$.

Similarly, from (2) we have

$$V_p = 0.00324967$$

$$\text{and } S.E. = 0.0570$$

It may be observed that the estimate of p is not significantly different from the experimental results² 0.39.

Fig. 1. (a) Docken-leaf and (b) normal, compound pinnate leaf of shoots after X-ray treatment

According to the correct estimates of p and q , the expected frequencies of disomic, monosomic and nullisomic presented in Table 2 in our communication¹ will be as follows:

Types	Disomic	Monosomic	Nullisomic	Total	χ^2
Chromosome No (42)	(41)	(40)			(d.f. 1)
Obs.	13	43	58	114	
Exp.	9.66	48.28	56.06	114.00	1.80

PSYCHOLOGY

Memory Changes with Age

MANY studies have shown that increasing age results in a deficiency in ability to acquire new skills and information. However, the commonly held view that older people manifest an impairment in the retention of acquired material has received equivocal support from laboratory investigations^{1,2}. Even Inglis's recent demonstration³ of a loss with age in short-term memory is confined to an hypothesized storage system with a limit of approximately 4 sec. I wish to direct attention to the results of an experiment which suggests that the aged show special defects in the remembering of acquired material stored over longer periods of time. These defects seem to be due to a loss in ability to retrieve memories from storage rather than a deficiency in the storage system itself.

The material for the experiment consisted of two lists of 24 words. The words were presented on a screen at intervals of 4 sec. Memory was tested by the voluntary recall method on one list and the recognition method on the other list immediately after the last word on a list was exposed. For the recognition method, subjects were shown the 24 learning words, each in a group of four other words, and asked to underline those previously seen on the screen. One hundred and thirty-four subjects, aged between twenty and seventy-five, participated in the experiment, with approximately half the group performing the recognition test first, the others beginning with the recall test.

The scores showed no significant differences between results on the recognition test when this preceded or followed the recall test on the alternate list. Similarly, there was no difference between recall scores when these were obtained before or after a recognition test. The results on the two lists have, therefore, been combined.

Table 1 shows that there is no deterioration with age in the recognition scores, while there is a consistent drop in the recall scores. The differences between recognition and recall scores shown in the final column have a ρ correlation with age groups of +1.00. The Pearson product moment correlation between individual recognition minus recall scores and age is +0.66 ($P < 0.001$).

The age disparity between recognition and recall scores cannot be due to a difference at the acquisition stage since this should affect both types of memory tests. The disparity must, therefore, be the result of the different demands of the two testing procedures. The psychological distinction between voluntary recall and recognition seems to be that the former requires retrieval from storage while the latter does not. In the recognition test, a response is provided and the subject needs only to match a stimulus

with the stored trace. These findings, therefore, suggest that age-related impairment of long-term memory may be confined to situations which involve the retrieval of acquired material from storage.

The work described was supported by grant APA-89 from the Canada National Research Council; the testing was carried out by Miss Betty-Anne Robertson.

MISCELLANEOUS

Ethology and the 'Baconian' Method

AMONG the many stimulating ideas elaborated by Sir Peter Medawar in his Presidential Address¹ to Section D of the British Association for the Advancement of Science is the claim that the foundation and subsequent development of what has come to be known as 'ethology' have "demonstrated the sterility of the old experimental approach" of test-stimulus and response, and illustrate "the danger of doing experiments in the Baconian style; that is to say, the danger of contriving 'experiences' intended merely to enlarge our general store of empirical knowledge rather than to sustain or confute a specific hypothesis or pre-supposition".

This rejection, by one with Sir Peter's authority, of the notion of a unique 'scientific method' applicable to all natural enquiry will fall gratefully on the ears of many. Nor can it be denied that the 'older experimental method' exemplified the weaker aspect of Bacon's incompletely worked out 'inductive method'. But does not Sir Peter imply a contrast that is in fact absent? For, in describing the 'new' and, in his view, effective ethological method, he says, "They [the pioneers of ethology] studied natural behaviour instead of contrived behaviour, and were thus able for the first time to discern natural behaviour structures or episodes—a style of analysis helped very greatly by the comparative approach." In the *Distributio Operis* prefixed to the *Instauratio magna* Bacon says, "all depends on keeping the eye steadily fixed upon the facts of nature and so receiving their images simply as they are. For God forbid that we should give out a dream of our own imagination for a pattern of the world."

That this ideal did not suffice to effect the so-called 'scientific revolution' is now abundantly clear; nor is it the method by which sciences greatly advanced by reason of their simplifying assumptions can be further enlarged. But, where an almost infinite number of possible variables leads to an almost limitless possibility of complexity, there is no alternative but to "sit down before facts like a little child" (Faraday)—but all the facts, in as great a variety of natural circumstances as possible. "Then, and only then", Sir Peter concludes, "was it possible to start to obtain significant information from the study of contrived behaviour . . . for it is not informative to study variations of behaviour unless we know beforehand the norm from which the variants depart." Being more interested in the "mastery of Nature for the relief of Man's estate", Bacon applied the method of comprehensive observation to the wrong data. But, so far from giving support to the now fashionable use of the term 'Baconian' as a wholesale term of disparagement, Sir Peter has shown how fertile, even indispensable, the 'Baconian' method may be in the appropriate context.

FORTHCOMING EVENTS

(Meetings marked with an asterisk are open to the public)

Monday, November 29

INSTITUTION OF ELECTRICAL ENGINEERS, ELECTRONICS DIVISION (at Savoy Place, London, W.C.2), at 10 a.m.—Colloquium on "Integrated Circuits".

INSTITUTION OF MECHANICAL ENGINEERS, RAILWAY ENGINEERING GROUP (at 1 Birdcage Walk, Westminster, London, S.W.1), at 6 p.m.—Discussion on "Specification and Inspection of Railway Materials".

ROYAL SOCIETY OF ARTS (at John Adam Street, Adelphi, London, W.C.2), at 6 p.m.—Prof. Colin Cherry: "The Future of World Communication". (Last of three Cantor Lectures on "World Communication".)

ROYAL SOCIETY OF MEDICINE (at 1 Wimpole Street, London, W.1), at 3 p.m.—Prof. R. H. S. Thompson: "A Biochemical Approach to the Problem of Multiple Sclerosis" (Jephcott Lecture).

INSTITUTION OF ELECTRICAL ENGINEERS, LONDON GRADUATE AND STUDENT SECTION (at Savoy Place, London, W.C.2), at 6.30 p.m.—Symposium on "Control and Its Applications".

PLASTICS INSTITUTE, LONDON SECTION REINFORCED PLASTICS SUB-GROUP (at the Wellcome Building, Euston Road, London, N.W.1), at 6.30 p.m.—Mr. B. A. Clark and Mr. D. F. Bailey: "Some Aspects of Design and Construction of Reinforced Plastics Building Panels".

ROYAL GEOGRAPHICAL SOCIETY (at 1 Kensington Gore, London, S.W.7), at 8.15 p.m.—Mr. A. R. Hanbury-Tenison: "From the Orinoco to the Plate".

Tuesday, November 30

INSTITUTION OF ELECTRICAL ENGINEERS, ELECTRONICS DIVISION (at Savoy Place, London, W.C.2), at 9.30 a.m. and 2.30 p.m.—Colloquium on "Artificial Reverberation Techniques".

UNIVERSITY OF LONDON (in the Anatomy Theatre, University College, Gower Street, London, W.C.1), at 1.15 p.m.—Mr. H. S. Smith: "The Story of Nubia".*

ROYAL SOCIETY (at Burlington House, Piccadilly, London, W.1), at 2.30 p.m.—Anniversary Meeting.

UNIVERSITY OF LONDON (at King's College, Strand, London, W.C.2), at 5 p.m.—Prof. Ilmari Hustich (Finland): "Finland—a Developed and Underdeveloped Country".*

INSTITUTION OF CIVIL ENGINEERS (at Great George Street, London, S.W.1), at 5.30 p.m.—Mr. S. E. H. Ford and Mr. S. C. Elliott: "Investigation and Design of Plover Cove Water Scheme".

ROYAL INSTITUTION (at 21 Albemarle Street, London, W.1), at 5.30 p.m.—Prof. G. Porter, F.R.S.: "Chaos and Chemical Equilibrium". (Afternoon lecture for Sixth Form Boys and Girls from Schools in London and the Home Counties. To be repeated on December 1, 7 and 8.)

UNIVERSITY OF LONDON (at the London School of Hygiene and Tropical Medicine, Keppel Street, Gower Street, London, W.C.1), at 6.30 p.m.—Prof. R. Boyland: "The Causes of Cancer". (Tenth of fifteen lectures on "The Scientific Basis of Medicine" organized by the British Postgraduate Medical Federation).*

INSTITUTION OF MECHANICAL ENGINEERS, AUTOMATIC CONTROL GROUP (at 1 Birdcage Walk, Westminster, London, S.W.1), at 6 p.m.—Discussion on "Relevance of Control Theory to Optimum Design in Engineering".

SOCIETY FOR ANALYTICAL CHEMISTRY, ATOMIC-ABSORPTION SPECTROSCOPY GROUP (at the Chemical Society, Burlington House, Piccadilly, London, W.1), at 6.30 p.m.—Annual General Meeting, followed by Mr. G. I. Goodfellow: "Some Observations on the Application of Atomic Fluorescence Spectrometry to Trace Analysis".

Tuesday, November 30—Wednesday, December 1

IRON AND STEEL INSTITUTE (at the Heare Memorial Hall, Church House, Great Smith Street, London, S.W.1, and at the Offices of the Institute, 4 Grosvenor Square, London, S.W.1), at 10 a.m. daily—Autumn General Meeting.

Wednesday, December 1

INSTITUTION OF ELECTRICAL ENGINEERS, ELECTRONICS DIVISION (joint meeting with the I.E.R.E., at Savoy Place, London, W.C.2), at 2 p.m.—Discussion on "Telemetry in Medicine".

SOCIETY FOR ANALYTICAL CHEMISTRY, THIN-LAYER CHROMATOGRAPHY GROUP (at the Chelsea College of Science and Technology, Manresa Road, London, S.W.3), at 2.15 p.m.—Annual General Meeting, followed by Mr. J. W. Grindlay, Mr. P. M. Wraight and Mr. J. C. Wright: "A Study of the Oxidation of Nitroso-Aromatics to Nitro-Aromatics in Propellant Stabilisers Using T.L.C. and Mass-Spectrometry"; Mr. G. B. Campbell: "The Determination of Antioxidants and Other Additives in Plastics by T.L.C."; Mr. J. Scotney: "Study of the Auto-Oxidation of Lanosterol by T.L.C.". *

INSTITUTION OF MECHANICAL ENGINEERS, AUTOMATIC CONTROL GROUP (at 1 Birdcage Walk, Westminster, London, S.W.1), at 4.30 p.m.—Three papers on "High-Reliability Servos".

ROYAL STATISTICAL SOCIETY (at the London School of Hygiene and Tropical Medicine, Keppel Street, Gower Street, London, W.C.1), at 6 p.m.—Mr. E. Seneta: "Stationary Distribution and Time-Reversion in Genetics".

UNIVERSITY OF LONDON (at King's College, Strand, London, W.C.2), at 6 p.m.—Prof. Ilmari Hustich (Finland): "The Polar Timber (Forest) Line".*

ROYAL SOCIETY OF MEDICINE, HISTORY OF MEDICINE SECTION (at 1 Wimpole Street, London, W.1), at 5.15 p.m.—Prof. A. Sorsby: "Gregor Mendel—Some Biographical Aspects"; Prof. E. B. Ford: "Mendelian Heredity and the Polymorphism Concept in Medicine" (Mendel Commemoration Meeting).

INSTITUTE OF PETROLEUM (at 61 New Cavendish Street, London, W.1), at 5.30 p.m.—Mr. A. S. Plane: "Calculation and Measurement of Quantities of Oil and Gas Evolved in Five-Stage Separation of Reservoir Crude".

INSTITUTION OF CIVIL ENGINEERS, HYDROLOGICAL GROUP (at Great George Street, London, S.W.1), at 5.30 p.m.—Informal Discussion on "Obtainable and Desirable Accuracies in Gauging Structure" introduced by Prof. J. R. D. Francis.

INSTITUTION OF ELECTRICAL ENGINEERS, POWER DIVISION (at Savoy Place, London, W.C.2), at 5.50 p.m.—Mr. N. W. Notani, Mr. T. B. Burnett and Mr. J. H. Cheetham: "Parallel Operation of Transducer-Controlled Silicon-Rectifier Equipment with Waterwheel-Driven D.C. Generators Supplying an Aluminium Potline".

INSTITUTION OF ELECTRONIC AND RADIO ENGINEERS, ELECTRO-ACOUSTICS GROUP (at 9 Bedford Square, London, W.C.1), at 6 p.m.—Dr. V. G. Welsby: "Non-Linear Effects in Acoustics, Radio and Optics".

PHARMACEUTICAL SOCIETY OF GREAT BRITAIN (at 17 Bloomsbury Square, London, W.C.1), at 6 p.m.—Mr. A. G. Fishburn: "The Future of the Pharmaceutical Sciences" (Harrison Memorial Lecture).

SOCIETY OF ENVIRONMENTAL ENGINEERS, PACKAGING GROUP (in the Mechanical Engineering Department, Imperial College, London, S.W.7), at 6 p.m.—Mr. D. G. Evans: "Atmospheric Corrosion".

Thursday, December 2

IRON AND STEEL INSTITUTE, ENGINEERS GROUP (at 4 Grosvenor Square, London, S.W.1), at 10 a.m.—Meeting on "Weighing in Iron and Steelworks".

ROYAL INSTITUTION OF Naval ARCHITECTS (in the Weir Lecture Hall, 10 Upper Belgrave Street, London, S.W.1), at 5 p.m.—Prof. E. V. Telfer: "Sir Charles Parsons and the Naval Architect" (Sir Charles Parsons Memorial Lecture).

INSTITUTION OF ELECTRICAL ENGINEERS (at Savoy Place, London, W.C.2), at 5.30 p.m.—Mr. J. A. Ratcliffe, F.R.S.: "Appleton's Contribution to Radio Science" (First Appleton Lecture).

UNIVERSITY OF LONDON (at the London School of Hygiene and Tropical Medicine, Keppel Street, Gower Street, London, W.C.1), at 5.30 p.m.—Dr. G. Alan Rose: "Some Thoughts on Osteoporosis and Osteomalacia" (Eleventh of fifteen lectures on "The Scientific Basis of Medicine" organized by the British Postgraduate Medical Federation).*

INSTITUTE OF REFRIGERATION (at the National College for Heating, Ventilating, Refrigeration and Fan Engineering, Southwark Bridge Road, London, S.E.1), at 6 p.m.—Mr. W. A. Hines: "The Control of Air Conditioning Plant Noise in Buildings".

INSTITUTION OF MECHANICAL ENGINEERS, EDUCATION AND TRAINING GROUP (at 1 Birdcage Walk, Westminster, London, S.W.1), at 6 p.m.—Discussion on "Should Engineering Science be a G.C.E. Subject Taught in Schools?".

SOCIETY OF CHEMICAL INDUSTRY, LONDON SECTION (joint meeting with the Microbiology Group, at 14 Eelgrave Square, London, S.W.1), at 6 p.m.—Dr. W. Howard Hughes and Dr. P. N. Cardew: "The Technique and Application of Time-lapse Cinemicrography"; Mr. R. S. M. Revell: "The Use of the Electron Microscope in Microbiology".

SOCIETY FOR ANALYTICAL CHEMISTRY, THERMAL ANALYSIS GROUP (at the Chemical Society, Burlington House, Piccadilly, London, W.1), at 6.30 p.m.—Annual General Meeting, followed by Dr. D. Fitzgerald: "Coal Carbonization Kinetics—Simple Thoughts on a Complex Matter"; Dr. S. C. Bevan and Mr. S. Thorburn: "The Analysis of Volatile Materials by Mass Detection Gas Chromatography".

ROYAL INSTITUTE OF CHEMISTRY, LONDON SECTION (joint meeting with the Northampton College Chemical Society, at the Northampton College of Advanced Technology, St. John Street, London, E.C.1), at 7 p.m.—Prof. C. E. H. Bawn, F.R.S.: "Cationic Polymerisation".

SOCIETY OF COSMETIC CHEMISTS OF GREAT BRITAIN (at the Royal Society of Arts, John Adam Street, Adelphi, London, W.C.2), at 7.30 p.m.—Mr. R. Stokes: "The Selection of Scientific Personnel".

Thursday, December 2—Friday, December 3

ROYAL PHOTOGRAPHIC SOCIETY (in conjunction with the Polytechnic School of Photography, at the Polytechnic, Regent Street, London, W.1)—Symposium on "Techniques in Applied Photography".

Friday, December 3

NUTRITION SOCIETY (at the Nuffield Institute of Comparative Medicine, Outer Circle, Regents Park, London, N.W.1), at 10 a.m.—Original Communications.

UNIVERSITY OF LONDON (at the Postgraduate Medical School of London, Du Cane Road, London, W.12), at 4 p.m.—Prof. W. S. Fearl: "The Renin/Angiotensin System".*

ROYAL ASTRONOMICAL SOCIETY (at Burlington House, Piccadilly, London, W.1), at 4.15 p.m.—Sir Edward Bullard, F.R.S.: "Electromagnetic Induction Within the Earth" (Third Harold Jeffreys Lecture).

ASSOCIATION OF SCIENTIFIC WORKERS (in the Kent Room, Caxton Hall, Westminster, London, S.W.1), at 6.30 p.m.—Discussion Conference on "Technology and the Nation's Needs" opened by Lord Snow, C.B.E.

SOCIETY OF CHEMICAL INDUSTRY, FINE CHEMICALS GROUP (at 14 Belgrave Square, London, S.W.1), at 6.30 p.m.—Dr. D. Jack: "Physicochemical Aspects of Drug Activity".

TELEVISION SOCIETY (in the Conference Suite, I.T.A., 70 Brompton Road, London, S.W.3), at 7 p.m.—Mr. B. Eastwood, Mr. A. Landman and Mr. P. L. Mothersole: "A Survey of Television Receiver Development".

Saturday, December 4

ASSOCIATION OF CLINICAL BIOCHEMISTS, SOUTHERN REGION (at Charing Cross Hospital Medical School, 62 Chandos Place, London, W.C.2), at 10 a.m.—Meeting on "Steroid Determination in the General Clinical Laboratory". Chairman: Prof. C. J. Gray.

INNER LONDON EDUCATIONAL AUTHORITY (at the Horniman Museum, London Road, Forest Hill, London, S.E.23), at 3.30 p.m.—Dr. I. M. Lewis: "Somaland—Peoples and Poets".*

Monday, December 6

UNIVERSITY OF LONDON (at the Postgraduate Medical School of London, Du Cane Road, London, W.12), at 4 p.m.—Dr. J. C. Gilson: "Asbestos, Recent Work on the Biological Importance of Fibre Type".*

INSTITUTION OF ELECTRICAL ENGINEERS, ELECTRONICS DIVISION (at Savoy Place, London, W.C.2), at 5.30 p.m.—Discussion on "Acoustic-Wave Amplification" opened by Dr. E. G. S. Paige and Mr. C. P. Sandbank.

INSTITUTION OF MECHANICAL ENGINEERS, THERMODYNAMICS AND FLUID MECHANICS GROUP (at 1 Birdcage Walk, Westminster, London, S.W.1), at 6 p.m.—Discussion on "Is Heat Transfer Theory of Any Use?"

ROYAL GEOGRAPHICAL SOCIETY (at 1 Kensington Gore, London, S.W.7), at 6 p.m.—"The Underwater Search" (Colour film).

SOCIETY OF CHEMICAL INDUSTRY, LONDON SECTION (Joint meeting with the Heavy Organic Chemicals Group, at 14 Belgrave Square, London, S.W.1), at 6.30 p.m.—Dr. H. L. Riley: "Recent Developments in the Tonnage Production of Aromatic Chemicals".

APPOINTMENTS VACANT

APPLICATIONS are invited for the following appointments on or before the dates mentioned:

CHAIR OF BOTANY AND HEAD OF THE DEPARTMENT—The Registrar, University of Leicester, Leicester (December 4).

CHAIR OF THEORETICAL PHYSICS—The Registrar, University of Leicester, Leicester (December 4).

LECTURER AND AN ASSISTANT LECTURER (graduates in sociology, psychology or history) IN THE DEPARTMENT OF SOCIOLOGY—The Registrar, University of Leicester, Leicester (December 4).

SENIOR LECTURER IN CONTROL ENGINEERING—The Registrar, University of Leicester, Leicester (December 4).

LECTURER IN THE DEPARTMENT OF PURE MATHEMATICS—The Registrar, University College of North Wales, Bangor, North Wales (December 6).

LECTURER (with a medical qualification) IN PHYSIOLOGY; and a JUNIOR LECTURER (with a medical qualification or an honours degree in physiology) IN PHYSIOLOGY—The Secretary, Trinity College (University of Dublin), Dublin 2, Republic of Ireland (December 6).

PROGRAMMER (with a degree or equivalent qualification, at least two years programming experience, and preferably a knowledge of Algol, Fortran or Elliot 803 machine code) IN THE COMPUTING LABORATORY to help in the provision of a computing service, by advising on the use of programmes and writing new programmes—The Registrar, University College of North Wales, Bangor, North Wales (December 6).

SENIOR LECTURER (with high academic qualifications and appropriate teaching and/or research experience) IN PHYSICS—The Principal, Lancaster College of Technology, Priory Street, Coventry (December 6).

LECTURERS IN PURE MATHEMATICS—The Registrar, The University of Warwick, Coventry, Warwickshire (December 10).

CHAIR OF PHYSICS—The Secretary, The Queen's University, Belfast, Northern Ireland (December 15).

LECTURER IN SOCIOLOGY at the University of Singapore—The Inter-University Council, 33 Bedford Place, London, W.C.1 (December 15).

LECTURER OR ASSISTANT LECTURER (medically qualified or non-medically qualified candidate) IN MEDICAL GENETICS to be responsible for cytogenetics—The Registrar, The University, Manchester, 13, quoting Ref 196/65/Na (December 15).

CHAIR OF MICROBIOLOGY—Secretary to the University Court, University of Glasgow, Glasgow (December 18).

SENIOR LECTURER (preferably with considerable teaching and research experience) IN THE DEPARTMENT OF PHILOSOPHY, University of Ghana—The Assistant Registrar, Ghana High Commission, Higher Education Section, 16 Gordon Square, London, W.C.1; or The Registrar, University of Ghana, P.O. Box 25, Legon, Accra, Ghana (December 18).

LECTURERS (2) (with a good honours degree and preferably with a minimum of two years experience in industry and/or research) IN THE DEPARTMENT OF CIVIL ENGINEERING—The Registrar, Queen Mary College (University of London), Mile End Road, London, E.1 (December 20).

RESEARCH ASSOCIATE (with a degree, preferably Ph.D., in physics, chemistry or metallurgy) IN CRYSTAL GROWTH IN THE DEPARTMENT OF PHYSICAL METALLURGY, to join an established research group working in the general field of crystal growth in metals and non-metals—The Assistant Registrar (Science and Engineering), University of Birmingham, Birmingham, 15 (December 22).

BOTANIST OR AGRICULTURAL BOTANIST (with a good honours degree) IN THE BIOCHEMISTRY DEPARTMENT, to study the factors affecting the production and extraction of leaf protein from agricultural crops and other plants—The Secretary, Rothamsted Experimental Station, Harpenden, Herts (January 1).

LECTURER (with a good honours degree and preferably teaching experience and a qualification and interest in logic) IN PHILOSOPHY at the University of Newcastle, New South Wales, Australia—The Association of Commonwealth Universities (Branch Office), Marlborough House, Pall Mall, London, S.W.1 (January 1).

CHAIR OF AGRONOMY within the Faculty of Agriculture, University of Western Australia—The Association of Commonwealth Universities (Branch Office), Marlborough House, Pall Mall, London, S.W.1 (Australia and London, January 15).

ENTOMOLOGISTS (2), NEMATOLOGISTS (2); a PLANT PATHOLOGIST (Mycologist); a SOIL CHEMIST; and a STATISTICIAN (Scientific Officer or Senior Scientific Officer grades)—The Secretary, Rothamsted Experimental Station, Harpenden, Herts (January 15).

PROFESSOR OF GEOPHYSICS (Solid Earth) at Victoria University of Wellington, New Zealand—The Association of Commonwealth Universities (Branch Office), Marlborough House, Pall Mall, London, S.W.1 (New Zealand and London, January 15).

LECTURER OR ASSISTANT LECTURER (man or woman graduate, preferably with qualifications and interest in social psychology) IN PSYCHOLOGY—The Secretary, Bedford College (University of London), Regent's Park, London, N.W.1 (January 30).

SENIOR LECTURER OR LECTURER (electrical engineer with experience of control problems in one of the process industries) IN CONTROL ENGINEERING IN THE DEPARTMENT OF SYSTEMS ENGINEERING—The Secretary, University of Lancaster, Bailrigg House, Lancaster (January 31).

RESEARCH TECHNICIAN OR SENIOR TECHNICIAN (woman, with a knowledge of histological and general laboratory techniques) for work with a medical research group—The Administrator, Department of Zoology, University of Oxford, Parks Road, Oxford.

GEO-TECHNOLOGY

Mineral Processing (Third Edition). E. J. Pryor

Formerly Reader in Mineral Dressing, University of London

Contents: General introduction; acceptance into the mill; primary crushing; secondary crushing; wet-grinding mills; forces in wet grinding; dry grinding; laboratory sizing control; industrial sizing and sorting; grinding circuit control; methods of separation; dense media separation; separation in vertical currents; separation in streaming currents; physics and chemistry in ore treatment; chemical extraction; principles of froth flotation; flotation practice; magnetic and electrical separation; testing and research; sampling and controls; unit processes and machines; selected ore treatments; appendices; index

140s.

The Mineral Resources of Africa. Nicolas de Kun

Department of Mining, Mineral Engineering and Metallurgy, Columbia University, New York

Contents: Part I. Industrial Development and Mineral Economics—Africa's share of world resources and production; the value of African production; the distribution of African output and resources; the history and development of mining; Northern Africa; Northeastern Africa; West Africa; Middle Africa; Southern Africa; the islands and the sea. Part II. Economic Geology—The mineralogical provinces of Africa; iron-bauxite group; gold group; base metal group; ultra-basic group; carbon-fuel group; sediments, miscellaneous; water and soil; appendices; index

240s.

The Mineral Resources of the Sea. John L. Mero

Newport News Shipbuilding and Dry Dock Co., Newport News, Va.

Contents: Preface; introduction; minerals from sea water, the continental shelves; strata underlying the soft sea-floor sediments; the deep-sea floor, ocean mining methods, some economic and legal aspects of ocean mining; appendices; references; index.

60s.

Sedimentology and Ore Genesis. Edited by G. C. Amstutz

Institute of Petrology and Mineralogy, University of Heidelberg, Germany

Contents: Introduction; redoxate deposits; oxidate deposits; sulphate and phosphate deposits; index.

55s.

The Techniques of Sedimentary Mineralogy. F. G. Tickell

Department of Mineral Engineering, Stanford University, Stanford, California

Contents: Introduction; size analysis; bulk properties; preparation of specimens; identification of minerals; description of minerals occurring in sedimentary rocks; appendices; references; index

90s

Identification of Mineral Grains. Meurig P. Jones and Marston G. Fleming

Department of Mining and Mineral Technology, Royal School of Mines, London

Contents: Introduction; summary of determinative scheme; list of equipment and reagents; procedure; recording test results; explanation of the determinative tables; references; alphabetical list of minerals; determinative table; index.

30s

Determination Tables for Ore Microscopy. C. Schouten

Technological University, Delft, The Netherlands

Contents: Preface; introduction; explanations and abbreviations; scheme of the tables; index

Cloth 55s, Paper 35s.

Pye precision in gas chromatography

Oven accommodates interchangeable head units incorporating different detector and column configurations and is designed for isothermal or programmed temperature control.

Oven head unit with dual flame detectors, columns and injection ports

NEW PYE SERIES 104 CHROMATOGRAPHS SPEED ROUTINE ANALYSES

Analysts are changing to the new low-cost Series 104 Chromatograph because its greater speed and convenience save money. They have acknowledged the functional design, the simplified operating features, the comprehensive specification and the overall economy of the system. They are now experiencing its complete reliability under continuous operating conditions.

Four versions of Series 104 are available which cover everyday analytical applications, including steroids, fatty acids, wide boiling range mixtures and high boilers.

The Pye Series 104 Chromatograph gives *faster analysis* with warm-up rates of up to 48°C per minute and operating temperatures as high as 500°C, *easier analysis* due to excellent oven accessi-

bility and design of controls, and *cheaper analysis* with lowest possible outlay and maintenance costs.

Moreover, the Pye Series 104 is designed for continuous development and updating as new techniques emerge. Please send for the new 20 page illustrated brochure which provides all the technical facts and figures including oven performance data.

PYE PANCHROMATOGRAPHS AID RESEARCH

Leading research establishments in many parts of the world depend upon the versatility of the Pye Panchromatograph to satisfy their most stringent requirements including investigations into the technique and the teaching of gas chromatography. This analytical system can accommodate different detector combinations and column arrangements in two independent ovens, and it features a patented column effluent splitting device which permits further analysis of the column outputs. Numerous optional features including temperature programming, pyrolysis, preparative scale and radiochromatography are available. The Pye Panchromatograph is the first choice for an all-purpose instrument for research.

The Panchromatograph will accommodate six different types of detector, singly or in pairs.

SERAVAC LABORATORIES (PTY.) LTD.

Moneyrow Green, Holyport,
Maidenhead, Berks., England.

GLASS

**All Glass Requirements for Scientific
Instrument Manufacturers and
Research Workers**

- SHEET & PLATE-GLASS—cut and ground to exact dimensions.
- LENSES, PRISMS & FLATS—to any standard of accuracy.
- MIRRORS—back silvered and front surface aluminised, etc.
- BLOOMING of optical components.

C. J. WHILEMS, LTD.

ILFORD OPTICAL WORKS

**FOREST ROAD, BARKINGSIDE,
ESSEX**

Telephone: HAInault 5454-5

**PRECISION INSTRUMENTS**

This Instrument, in its modern styling, still embodies the requirements laid down by Mr. Guild of the National Physical Laboratory and the advice of research workers in various laboratories.

- * CAN BE SUPPLIED WITH A DIFFERENTIAL CELL COMPLETE WITH COLLIMATOR AND SLIT FOR MEASUREMENT OF REFRACTIVE INDICES OVER THE RANGE 1.26 TO 1.95.

The interchangeable prisms, each covering a recommended range of refractive index, are of 60° refracting angle and are mounted in individual water jackets.

We are the sole distributors in the U.K. of Schott Monochromatic Interference Filters.

The Improved Type Pulfrich Refractometer

Please ask for Details 'N'.

SCIENCE, INVENTIVENESS AND CREATIVITY

IN a reference to Sir Peter Medawar's Tizard Memorial Lecture when addressing Section L (Education) at the Cambridge meeting of the British Association for the Advancement of Science, Sir Edward Boyle expressed the hope that Sir Peter would later develop, at greater length, his comment that the more creditable part of our reverence for pure science might derive from the accident that in Britain the quintessential form of activity had always been poetic invention. Sir Edward appeared to agree with Sir Peter that imaginative thought played an important part in discovery and invention, and also that imagination could be trained and guided and deliberately stocked with material for imaginative use. However, neither he nor Sir Peter pursued further the place which the imagination holds in creative work. Sir Peter, indeed, questioning the view of Coleridge as expounded in *The Road to Xanadu*, insisted that poetic inspiration was no valid guide to imaginative activity in all its forms.

Earlier in his Lecture, Sir Peter had recognized that a scientist must be freely imaginative and yet a sceptic, creative yet critical. His reference to the imaginative and creative aspect of scientific activity, to the distinctions which Haslett, Coleridge and Shelley had drawn between science and poetry, was designed essentially to support his argument that applied or commissioned science was in no way inferior to what we characterize as 'pure' science. This creative or imaginative aspect was, however, pursued in other addresses at Cambridge to the same section and also to Section X (General) at the pragmatic level. Mr. Gerd Sommerhoff revealed it in his address, 'Creative Technology', when he described to the Education section some of the work and philosophy of the Technical Activities Centre which he directs at Sevenoaks School. The theme was maintained, at the philosophical level, by Mr. A. Koestler in an address to Section X on evolution and revolution in the history of science. It also received some passing comment in Dr. Magnus Pyke's presidential address to the latter Section on "Scientific Understanding and the Chief End of Man".

Dr. Pyke early in his address repudiated the charge of materialism that is often brought against science. He agreed that scientific understanding had relieved us of much of the need to pre-occupy ourselves with providing food and that it could equally remove the burden of earning a living—if 'burden' is an appropriate word to use in that context. The most powerful impact of applied science on the daily life of human society lies in the reduction it makes possible in the proportion of time necessarily spent on paid work, but, as Dr. Pyke continued, food, health, material prosperity, and a happy communal life, though desirable in themselves, are not the chief end of man. A civilized community should also direct its efforts towards developing the general powers of the mind, which makes possible the attainment of a higher purpose.

To such a goal, scientific thinking has much to contribute, and it is at this point that, after quoting a passage from Robert Oppenheimer about the delight of a scientist in the experience of discovery, which reflects the motif of Sir Cyril Hinshelwood's opening address, Dr. Pyke con-

sidered the way in which science shared the same attributes as art as one of man's creative activities. He did not suggest that this applied to all scientific work and he made a scathing comment about published scientific work which failed to advance scientific understanding. Unlike Sir Edward or Mr. Koestler, he did not refer to Prof. Kuhn, but in this passage of his address Dr. Pyke's thoughts obviously ran on similar lines to those expressed by Prof. Kuhn in his book, *The Structure of Scientific Revolutions**. Dr. Pyke passed on swiftly to urge that modern society had been created by the peculiar application of intellectual logic and imagination in search of truth. The real schism in our culture, he believed, was between those who based their behaviour on dogma and assertion and those who put their faith in reason and the conviction that the exercise of reason aided by imagination in search of truth is the basic human goal. The whole universe of science is built on the belief that this is a rational universe.

Dr. Pyke affirmed his own belief that the chief end of man is a moral one. While he contended that scientific understanding was not morally neutral but must radically affect our attitude to moral values, he agreed with Prof. D. M. MacKay, of the University of Keele, that it was the concern for truth and the like which begot science, not science which begot the concern for truth. He stated that such ethical values were essential to the practice of science, and the more people we taught to be scientists the more we should disseminate these values. At every point, scientific understanding, with its fundamental insistence on intellectual honesty, has a bearing on moral values. In its essentials, the search for truth, the chief end towards which man is finding himself driven to strive, is the pursuit of a moral goal. Dr. Pyke quoted Dr. A. Szent-Gyorgyi's observations that morals are the simple prescriptions which make living together possible and that the basic moral rule of the living society of scientists is mutual respect, intellectual honesty and goodwill. Because scientific understanding compels a reappraisal of the codes we learned mostly as children it is not destructive of moral behaviour.

Mr. Koestler began his lecture by referring to the framework he has developed at length in his book, *The Act of Creation*, at least sufficiently to insist that any discussion of creativity must start with a frame of reference for the ordinary routines of behaviour, and to argue that organic life, in all its manifestations, is governed by rules, whether innate or acquired, which are represented in coded form at various levels from the genetic code to the structures in the nervous system responsible for symbolic thought. He suggested that spontaneous insight usually means the emergence of a new synthesis of a whole, at a higher level than that of the parts which combined and fused into it. The combinational activity he regards as the key to creativeness and he appears to draw the line between solving routine problems and creative originality in much the same way as Prof. Kuhn does in *The Structure of Scientific Revolutions*.

* *The Structure of Scientific Revolutions*. By Prof. Thomas S. Kuhn. Pp. xiv + 172. (Chicago and London: University of Chicago Press, 1964. Originally published 1962.) 1.50 dollars; 10s. 6d. net.

As criteria of what we call 'creativity', Koestler used, as in *The Act of Creation*, four factors: originality; the lack of relation between the matrices which enter into the combination or, in other words, improbability; the intervention of extra-conscious processes; and the constructive-destructive element, which Koestler, like Kuhn, regards as characterizing any scientific revolution. The true scientist, he observes, like the true artist, is an uneasy mixture of the adventurer and the pedant, and he again reminds us that science is made by scientists and not scientists by science. His overall view of science as advancing by evolutionary and revolutionary cycles, a zig-zag progress, not a curve approaching its asymptote, thus closely resembles that of Kuhn.

Obviously this view of scientific advance and of creativity has implications both for the relations of science and technology and for their teaching, particularly when the whole content of syllabuses is under review. Kuhn insists that a new theory, for example, however special its range of applications, is seldom or never just an increment to what is already known. Its assimilation requires the reconstruction of prior theory and the reconstruction of prior fact, an intrinsically revolutionary process that is seldom completed by a single man and never overnight. The unexpected discovery is not simply factual in its import and the world of the scientist is qualitatively transformed as well as quantitatively enriched by fundamental novelties either of fact or of theory.

Prof. Kuhn is not directly concerned with this teaching aspect or with the relations between science and technology. He is concerned rather with the scientific community, which he regards as unique among professional communities in the extent to which individual creative work is addressed to and evaluated by other members of the profession. Moreover, this is facilitated by the comparative insulation of the scientific community from society in general. In this context, Prof. Kuhn's remark that, unlike the engineer and many doctors, the scientist need not choose problems because they urgently need solution or without regard for the tools available to solve them indicates the distinction he does in fact draw between the pure and the applied scientist—a distinction which he also draws between the former and the social scientist.

This effect of insulation from the larger society does lead Prof. Kuhn to touch on education, though apart from the remark that scientific training is not well designed to produce the man who will easily discover a fresh approach, he is concerned chiefly with the transmission of knowledge through text-books. These, he asserts, are systematically substituted for creative scientific literature, until the very last stages in the education of a scientist. That statement is certainly more open to challenge than a comment about the neglect of the historical aspects, where fortunately there are now indications that the past neglect is being repaired, but more important, perhaps, is Kuhn's comment on the implications of authority in science.

The very existence of science depends on vesting the power to choose between paradigms or the conceptual framework within which a discipline functions in the members of a special kind of community. The very tenuousness of humanity's hold on the scientific 'enterprise' indicates how special that community must be if science is to survive and grow. If authority alone, and particularly non-professional authority, were the arbiter of paradigm debates, the outcome might still be revolu-

tion; but it would not be scientific revolution. Nevertheless, while Prof. Kuhn recognizes also that the bulk of scientific knowledge is a product of Europe in the past four centuries and that no other place and time has supported the very special communities from which scientific productivity comes, he does not follow Dr. Pyke or draw the conclusion which Dr. Pyke has done about the moral basis of such a community or society.

Valuable as a clear understanding of the creative process may be, neither Kuhn nor Koestler establish the desirability of creativity as an important objective in our educational system. The important matter here is to ensure that society provides sufficient opportunities for fruitful creative work in science and technology, as in art, and that those opportunities are available to trained men and women at an early stage in their professional career (or, as Prof. R. V. Jones puts it, to bring them to the frontiers of their subject before they are so exhausted by their journey through knowledge already won that they cannot make the next advance). It is, of course, essential that their education and their professional training should be such as to encourage the capacity for clear and independent thought as well as to develop the critical faculty and sound judgment. This applies to university or higher education generally, however, and is now being realized in the technical colleges as well as in the colleges of technology and the universities, as not only the contribution of Mr. A. D. C. Peterson on liberal education and the British technologist but also Mr. F. Metcalfe's on the idea of a technical college plainly showed. Mr. Metcalfe was fully aware of the difficulties and handicaps of the technical colleges, but his paper was noteworthy because it gave a most encouraging picture of the way in which these colleges are now tackling the human problems of developing a new maturity in their students. Such a maturity should do much to ease the problem of communication between different disciplines and illuminate and encourage the understanding of the social values of their work. It is perhaps here, even more than in the universities and colleges of technology, that we must look for scientific understanding to make its fullest impact on the moral and the social values of the society in which we live.

The importance of a clearer and wider understanding of the creative process is also shown by a recent article in *Chemistry and Britain* (1, 449; October 1965). Under the title "Planning for Invention in Science-Based Industry", what is discussed is not so much the climate for invention, but rather the equally important problem of selecting the right projects; curiously enough, however, there is no reference to the difficult problem of deciding when to break off a project. It is true that the writer recognizes the importance of selecting staff with the right mental requirements and of ensuring effective communications, but the value of the article lies not in its contribution to the promotion of creative work but in its emphasis on the changes which the selection of problems now requires in the administration of research.

Now that most of the 'easy' problems have been solved, it is harder to obtain successful results in research, and this factor increases the importance of the research team, including specialists in various disciplines. The more penetrating background knowledge now available has, however, greatly increased the chances of solving the newer and more difficult problems. However, while research and invention remain as easy or difficult, and as challenging a routine because the two factors offset each other, the administrator of research must increasingly

strive to see that ideas are sought in the desired fields, and to choose those special fields correctly. It is obvious that this, in itself, could have profound implications for the balance between pure and applied science.

Leaving that aspect, however, the article in itself shows how timely is the decision which has led to the Summer 1965 issue of *Daedalus*, the journal of the American Academy of Arts and Sciences, being devoted to the subject of creativity and learning. Some of the essays, notably those of J. B. Wiesner on education for creativity in the sciences, Prof. L. S. Kubie on unsolved problems of scientific education, Dr. P. H. Abelson on relation of group activity to creativity in science, and Prof. E. P. Torrance on scientific views of creativity and factors affecting its growth, manifestly overlap with discussions at the Cambridge meetings of the British Association. This is also true, to a lesser degree, of Prof. D. Hawkins's essay on science education, "The Informed Vision", Prof. L. Eiseley's discussion of Darwin, Coleridge and the theory of unconscious creation, which is supported by an admirable bibliography, and Prof. J. D. Brown's essay on the development of creative teacher-scholars, on those who provide the vital core of a dynamic teaching university.

Not only does Prof. Brown maintain that a creative scholar provides a flow of new ideas, drawing on deep resources of accumulated knowledge; the art of teaching, well performed, is itself creative. He is well aware that he is concerned with only a small but precious minority, and that, while we can encourage the development of some attributes like the power of analysis and accumulation, the practice of self-discipline, or introspection, and resistance to external authority, with others like the inquiring mind, and most important of all, intuition, we can only hope to avoid dulling or repressing. He does not attempt to write a prescription for the development of a faculty of creative teacher-scholars but rather to point out some of the dangers which administration should seek to avoid; however, he recognizes that leadership and tradition have a contribution to make. Moreover, Prof. Brown reminds us that the true test of a good teacher is what he does to his students—developing their powers of clear thinking, analysis, orderly accumulation, evaluation and re-creation of ideas in their own terms. Higher education which fails to do just this is missing its objective and becomes a waste of precious resources.

There are other challenges to the thought and practice at present accepted in higher education in Britain, whether in science or technology, or in other fields, to be found in this symposium. Dr. Abelson, for example, considers the crucial element in creativity in science to-day is not dramatic illumination but judgment—a view which

would appear to put him with Koestler and Kuhn—though he does not ignore the importance of motivation and self-discipline. Torrance believes we have long known enough about the factors affecting creative growth to make a much better effort at creative education. His own investigations have convinced him that different kinds of children learn best when given opportunities to learn in ways best suited to their motivations and abilities, and he suggests that significant changes in methods of teaching could lead to many more people achieving a higher level of education as well as greater dignity and mental health in our society.

One of the most interesting contributions is that from Dr. Wiesner, who begins with some challenging remarks about professional obsolescence. Admittedly, he limits his assertion to the research or design engineer, but it may well be questioned whether ten years is, in fact, the longest time such a technologist can expect to be effective to-day without a continuing education or a major effort to refurbish his basic and specialized professional skills. If that is true, the validity of the original professional training may well be questioned, though no one would doubt that most new ideas come from a very small number of working scientists and technologists or that there is a scarcity of those with developed creative gifts.

Dr. Wiesner draws a distinction between creativity and productivity which is suggestive of Prof. Kuhn's thinking. A new idea or concept may be creative in a philosophical or artistic sense but, to be considered scientifically productive, it must also meet the criterion of being logically related, in quantitative terms, to the body of science. From this, he argues that creativity is a more general term than productivity and that when 'creativity' or 'creative' are used in association with science and technology, it is to be assumed that productivity is also involved.

The point is scarcely developed at sufficient length to command general assent before Dr. Wiesner proceeds to discuss the kinds of creative activity which society expects from scientists and technologists. Limiting that expectation, as he does, to scientific research, to applied scientific and technological research, and to engineering design, his thesis may perhaps be more readily accepted. Pointing out, however, that the student with a large fund of knowledge, polished techniques, and a total lack of creative ability is too common a product of our system, he emphasizes the need, at both school- and university-level, for education reform based on an adequate programme of research, if we are to develop the latent creative ability of our students—a conclusion which was also implicit in the Cambridge discussions.

TECHNICS AND THE NATURE OF MAN*

By LEWIS MUMFORD

President of the American Academy of Arts and Letters

THE last century, we all realize, has witnessed a radical transformation in the entire human environment, largely as a result of the impact of the mathematical and physical sciences on technology. This shift from an empirical, tradition-bound technics to an experimental

scientific mode has opened up such new realms as those of nuclear energy, supersonic transportation, cybernetic intelligence, and instantaneous planetary communication.

In terms of the currently accepted picture of the relation of man to technics our age is passing from the *primaeva* state of man, marked by his invention of tools and weapons for the purpose of achieving mastery over the forces of Nature, to a radically different condition, in which he will

* Substance of a paper read during the bicentennial celebrations commemorating the birth of James Smithson, held in Washington during September 16-18 (see *Nature* of October 23, p. 321).

not only have conquered Nature but detached himself completely from the organic habitat. With this new macro-technology, man will create a uniform, all-enveloping structure, designed for automatic operation. Instead of functioning actively as a tool-using animal, man will become a passive, machine-serving animal whose proper functions, if this process continues unchanged, will either be fed into a machine, or strictly limited and controlled for the benefit of depersonalized collective organizations. The ultimate tendency of this development was correctly anticipated by Samuel Butler more than a century ago: but it is only now that his playful fantasy shows many signs of becoming a far-from-playful reality.

My purpose in this article is to question both the assumptions and the predictions on which our commitment to the present form of technical and scientific progress, as an end itself, has been based. In particular, I find it necessary to cast doubts on the generally accepted theories of man's basic nature which have been implicit during the last century in our constant over-rating of the role of tools and machines in the human economy. I shall suggest that not only was Karl Marx in error in giving the instruments of production a central place and a directive function in human development, but even the seemingly benign interpretation by Teilhard de Chardin reads back into the whole story of man the narrow technological rationalism of our own age, and projects into the future a final state in which all the further possibilities of human development would come to an end, because nothing would be left of man's original nature that had not been absorbed into, if not suppressed by, the technical organizations of intelligence into a universal and omnipotent layer of mind.

Since the conclusions I have reached require, for their background, a large body of evidence I have been marshalling in a still unpublished book, I am aware that the following summary must, by its brevity, seem superficial and unconvincing. At best, I can only hope to show that there are serious reasons for reconsidering the whole picture of both human and technical development on which the present organization of Western society is based.

Now, we cannot understand the role that technics has played in human development without a deeper insight into the nature of man: yet that insight has itself been blurred, during the past century, because it has been conditioned by a social environment in which a mass of new mechanical inventions has suddenly proliferated, sweeping away many ancient processes and institutions, and altering our very conception of both human limitations and technical possibilities.

For a century man has been habitually defined as a tool-using animal. This definition would have seemed strange to Plato, who attributed man's rise from a primitive state as much to Marsyas and Orpheus as to Prometheus and Hephaestus, the blacksmith-god. Yet the description of man as essentially a tool-using and tool-making animal has become so firmly accepted that the mere finding of the fragments of skulls, in association with roughly shaped pebbles, as with Dr. L. S. B. Leakey's Australopithecines, is deemed sufficient to identify the creature as a proto-human, despite marked physical divergences from both earlier apes and later men.

Two substantial errors are embedded in this general interpretation. The first is the unintentional distortion of evidence, through the fact that the only durable remains of either early man or his hominid ancestors are an extremely scanty supply of bones and stones, presumably tools—though, apart from grubbing, pounding and ripping, one can only guess what purpose they served. The durability of stone artefacts has given this part of man's technical equipment a prominence it could never have claimed if the far richer store of organic materials, which early man shared with many primate ancestors, had been preserved. But it is an illusion to suppose that man's

technical development was confined to exploiting stone quarries, to flint-chipping, to the manipulation of tools alone: for the source of man's early technics was the whole natural environment—edible plants and animals, vines, leaves, shells, reeds, twigs, bark, fibre, skins—all of which, save the last, can be utilized without other tools than man's own unaided teeth and hands.

By fastening attention on the surviving stone artefacts, many anthropologists and ethnologists have gratuitously attributed to the shaping and using of tools the enlargement of the human brain and therewith the development of man's higher intelligence, though motor-sensory co-ordinations involved in this elementary manufacture do not call for or evoke any considerable mental acuteness. Since the sub-hominids of South Africa had a brain capacity about a third of *Homo sapiens*, no greater indeed than that of many apes, the capacity to make tools neither called for nor generated early man's rich cerebral equipment, as Dr. Ernst Mayr of Harvard has recently pointed out.

The second error in interpreting man's nature is a less pardonable one, since Francis Bacon should long ago have put scientists on guard against it; and that is, the present-day tendency to read back into prehistoric times modern man's overwhelming interest in tools and machines, to the exclusion of equally important items of technical equipment. Tools and weapons are specialized extrapolations of man's own organs for pushing, pounding, crunching, cutting, stabbing—all basic motor activities. No one can doubt that these dynamic processes, which man shares with many other species, formed an essential part of his earliest technical complex.

But just because man's need for tools is so obvious, we must guard against over-emphasizing the role of tools hundreds of thousands of years before they became functionally efficient. In treating tool-making as central to the palaeolithic economy, ethnologists have underplayed, or neglected, a mass of activities in which many other species were for long far more knowledgeable than man. Despite the contrary evidence put forward by R. V. Sayce, Daryll Forde and Andre Leroi-Gourhan, there is still a tendency to identify tools and machines with technology: to substitute a part for the whole. Even in describing only the material components of technics, this practice overlooks the equally vital role of containers: hearths, pits, houses, pots, sacks, clothes, traps, bins, byres, baskets, bags, ditches, reservoirs, canals and cities. These static components play an important part in every technology, not least in our own day, with its high tension transformers, its giant chemical retorts, its atom-reactors.

In any comprehensive definition of technics, it should be plain that many insects, birds and mammals had made far more radical innovations in the fabrication of containers, with their intricate nests and bowers, their geometric beehives, their urbanoid ant-hills and termitaries, than man's ancestors had achieved in the making of tools until the emergence of *Homo sapiens*. In short, if technical proficiency were alone sufficient to identify potential intelligence, man would, for long, have been rated a hopeless dunder alongside many other species. The consequences of this perception should be plain; namely, that there was nothing uniquely human in early technology until it was modified by linguistic symbols and aesthetic designs. At that point the human mind, not just the hand, made a profound difference.

At the beginning, then, I suggest that the human race had achieved no special position by reason of its tool-using or tool-making propensities alone. Or rather, man at the beginning possessed one primary all-purpose tool that was more important than any later assemblage: namely, his own mind-activated body, every part of it not just those motor activities that produced hand axes and wooden spears. To compensate for his extremely primitive working gear, early man had a much more

important asset that widened his whole technical horizon: he has a far richer biological equipment than any other animal, a body not specialized for any single activity, but, precisely because of its extraordinary plasticity, more effective in using a larger portion of both his external environment and his internal psycho-somatic resources.

Through man's over-developed and incessantly active brain, he had more mental energy to tap than he needed for survival at a purely animal level; and he was, accordingly, under the necessity of canalizing that energy, not just into food-getting and reproduction, but into modes of living that would convert this energy more directly and constructively into appropriate cultural—that is, symbolic—forms. Cultural work, by necessity, took precedence over manual work; this involved far more than the discipline of hand, muscle and eye in making and using tools. It likewise demanded a control of all man's biological functions, including his bodily organs, his emotions, his sexual activities, his dreams. Even the hand was no mere horny work-tool: it stroked a lover's body, held a baby close to the breast, made significant gestures, or expressed in ordered dance and shared ritual some otherwise inexpressible sentiment about life or death, a remembered past or an anxious future. Tool-technics is but a fragment of bio-technics: man's total equipment for life.

On this view, one may well hold it an open question whether the standardized patterns and the repetitive order which came to play such an effective part in the development of tools from an early period, as Braidwood has pointed out, derive solely from tool-making. Do they not rather derive even more, perhaps, from the forms of ritual, song and dance-forms which exist in a state of perfection among primitive peoples, often in a far more exquisitely finished state than their tools? There is, in fact, widespread evidence, first noted by Hocart, that ritual exactitude in ceremony preceded mechanical exactitude in work: that the first rigorous division of labour came through specialization in ceremonial offices.

These facts help to explain why simple peoples who easily get bored by purely mechanical tasks which might improve their physical well-being, will, nevertheless, repeat a meaningful ritual often to the point of physical exhaustion. The debt of technics to play and to play-toys, to myth and fantasy, to magic rite and religious rote, which, called attention to in "Technics and Civilization", has still to be sufficiently recognized, though J. Huizinga, in *Homo Ludens*, went so far as to treat play itself as the basic formative element in all culture.

Tool-making, in the narrow technical sense, may, indeed, go back to our hominid African ancestors. But the technical equipment of Chellean and Acheulian times remained extremely limited until a more richly endowed creature, with a nervous system nearer to that of *Homo sapiens* than to any primaeval hominid predecessors, had come into existence, and brought into operation not alone his hands and legs but his entire body and mind, projecting them, not just in tools and utensils but in more purely symbolic non-utilitarian forms.

In this revision of the accepted technological stereotypes, I would go even further: for I submit that at every stage, man's technological expansions and transformations were less for the purpose of increasing the food supply or controlling Nature, than for utilizing his immense actual resources, and expressing his latent potentialities, in order to fulfil more adequately his own unique super-organic needs. When not threatened by a hostile environment, the elaboration of symbolic culture was a more imperative need than control over the external environment—and, as one must infer, largely pre-dated it, and for long out-paced it.

On this reading, the invention of language—a culmination of man's more elementary forms of expressing and transmitting meaning—was incomparably more important to further human development than the chipping of a

mountain of hand axes. Beside the relatively simple co-ordinations required for tool-using, the delicate interplay of the many organs needed for the creation of articulate speech was a far more striking advance, and must have occupied a great part of early man's time, energy and mental concentration, since its collective product, language, was infinitely more complex and sophisticated at the dawn of civilization than the Egyptian or Mesopotamian kit of tools. For only when knowledge and practice could be stored in symbolic forms, and passed on by word of mouth from generation to generation, was it possible to keep each fresh cultural acquisition from dissolving with the passing moment or the dying generation. Then, and then only, did the domestication of plants and animals become possible. Need I remind you that this decisive technical transformation, sometimes termed a revolution, was achieved with no better tools than the digging stick, the axe, the mattock? The plough, like the cart-wheel, came later as a specialized adaptation to the large-scale field cultivation of grain.

To consider man as primarily a tool-using animal, then, is to overlook the main chapters of human prehistory. Even when one considers the technical milieu alone, this concentration on the dynamic components results in our having long treated as negligible that vast area of technics in which man's control of chemical changes through heat and fermentation, leaching and sterilizing—as in brewing, burning, melting, tanning, cooking—favourably modified the conditions of human existence. Opposed to this stereotype is the view that man is pre-eminently a mind-using, self-mastering animal; and the primary locus of all his activities is his own organism. Until he had made something of himself, he could make little of the world around him.

In this process of self-discovery and self-transformation, technics, in the narrow sense, served well as a subsidiary instrument, but not as the main operative agent in man's development; for technics was never until our own age dissociated from the larger cultural whole in which man—as man—has always functioned. Early man's original development was based on what Andre Varagnac happily called "the technology of the body": the utilization of man's highly plastic bodily capacities for the expression of his still unformed and uninformed mind, before that mind had yet achieved, through the development of symbols and images, its own more etherealized technical instruments. From the beginning, the creation of significant modes of symbolic expression, rather than more effective tools, was the basis of the further development of *Homo sapiens*. In approaching this conclusion I happily find myself reaching, by a quite independent route, Prof. Levi-Strauss's conception of cultural determinants.

Unfortunately, so firmly were the prevailing nineteenth-century conceptions committed to the notion of man as primarily *Homo faber*, the tool-maker, rather than *Homo sapiens*, the mind-maker, that, as is known, the first discovery of the art of the Altamira caves was dismissed as a hoax, because the leading palaeo-ethnologists would not admit that the Ice Age hunters, whose weapons and tools they had recently discovered, could have had either the leisure or the mental inclination to produce art—not crude forms, but images that showed powers of observation and abstraction of a high order. But when we compare the carvings and paintings of the Aurignacian or Magdalenian finds, with their surviving technical equipment, who shall say whether it is art or technics that shows the highest development? Even the finely finished Solutro laurel leaf points were plainly a gift of aesthetically sensitive artisans to functional efficiency. The Greek form for 'techniques' makes no distinction between industrial production and symbolic art; and for the greater part of human history these aspects were inseparable, one side respecting objective conditions and functions, the other responding to subjective needs.

Our age has not yet overcome the peculiar utilitarian bias that regards technical invention as primary, and aesthetic expression as secondary or superfluous; and this means that we have still to acknowledge that technics derives from the whole man, in his intercourse with every part of the environment, utilizing every aptitude in himself to make the most of his own biological and ecological potentials.

Even at the earliest stage, trapping and foraging called less for tools than for sharp observation of animal habits and habitats, backed by a wide experimental sampling of plants and shrewd interpretation of the effects of various foods, medicines and poisons on the human organism. And in those horticultural discoveries which, if Oakes Ames was right, must have preceded by many thousands of years the active domestication of plants, taste and formal beauty played a part no less than their food value; so that the earliest domesticates, other than the grains, were often valued for the colour and form of their flowers, for their perfume, their texture, their spiciness, rather than merely for nourishment. Edgar Anderson has suggested that the neolithic garden, like the gardens in many simple cultures to-day, was probably a mixture of food plants, dye plants and ornamentals—all treated as equally essential for life.

Similarly, some of early man's most daring technical experiments had nothing whatever to do with the mastery of the external environment: they were concerned with the anatomical modification or the superficial decoration of the human body, for sexual emphasis, self-expression, or group identification. The Abbé Breuil found evidence of such practices as early as the Mousterian culture, which served equally in the development of ornament and surgery. Plainly, tools and weapons, so far from dominating man's technical equipment, as the petrified artefacts too glibly suggested, constituted a small part of the biotechnical assemblage; and the struggle for existence, though sometimes severe, did not engross the energy and vitality of early man, or divert him from his more central need to bring order and meaning into every part of his life. In that larger effort, ritual, dance, song, painting, carving and, above all, discursive language—arts which utilize all the organs of the body—must for long have played a decisive role.

At its points of origin, then, technics was related to the whole nature of man, and that nature played a formative part in the development of every aspect of technology: thus technics at the beginning was broadly life-centred, not work-centred or power-centred. As in all ecological complexes, other human interests and purposes, other organic needs, restrained the overgrowth of any single component. As for the greatest technical feat before our own age, the domestication of plants and animals, this advance owed almost nothing to new tools, though it encouraged the development of clay containers. But it owed much, we now begin to realize, since Edouard Hahn, to an intense subjective concentration on sexuality in all its manifestations, abundantly visible in cult objects and symbolic art. Plant selection, hybridization, fertilization, manuring, seeding and castration were the products of an imaginative cultivation of sexuality, the first evidence of which one finds tens of thousands of years earlier in the emphatically sexual carvings of palaeolithic woman: the so-called Venuses.

But at the point where history, in the form of the written record, becomes visible, that life-centred economy, a true polytechnics, was challenged and in part displaced in a series of radical technical and social innovations. About five thousand years ago, a monotecnics, devoted to the increase of power and wealth by the systematic organization of workaday activities in a rigidly mechanical pattern, came into existence. At this moment, a new conception of the nature of man arose, and with it a new stress on the exploitation of physical energies, cosmic and human, apart from the processes of growth and reproduction,

came to the fore. In Egypt, Osiris symbolizes the older, life-oriented techniques: Atum-He, the Sun God, who characteristically created the world out of his own semen without female co-operation, stands for the machine-centred one. The expansion of power, through ruthless human coercion and mechanical organization, took precedence over the enhancement of life.

The chief mark of this change was the construction of the first complex, high-powered machines; and therewith the beginning of a new regimen, accepted by all later civilized societies—though reluctantly by more archaic cultures—in which work at a single specialized task, segregated from other biological and social activities, not only occupied the entire day, but increasingly engrossed the entire lifetime. That was the fundamental departure which, during the past few centuries, has led to the increasing mechanization and automation of all production. With the assemblage of the first collective machines, work, by its systematic dissociation from the rest of life, became a curse, a burden, a sacrifice, a form of punishment: and by reaction this new regimen soon awakened compensatory dreams of effortless affluence, emancipated not only from slavery but from work itself.

The machine I refer to was never discovered in any archaeological diggings, for a simple reason: it was composed almost entirely of human parts. These parts were brought together in a hierarchical organization under the rule of an absolute monarch, the commands of whom, supported by a coalition of the priesthood, the armed nobility, and the bureaucracy, secured a corpse-like obedience from all the components of the machine. Let us call this archetypal machine—the human model for all later specialized machines—the 'Megamachine'. This new kind of machine was far more complex than the contemporary potter's wheel or bow-drill, and it remained the most advanced type of machine until the invention of the mechanical clock in the fourteenth century.

Only through the deliberate invention of such a high-powered machine could the colossal works of engineering that marked the Pyramid Age in both Egypt and Mesopotamia have been brought into existence, often in a single generation. This new technics came to an early climax in the Great Pyramid at Giza. That structure, as J. H. Breasted pointed out, exhibited a watchmaker's standard of exact measurement. By operating as a mechanical unit, the 100,000 men who worked on that pyramid generated ten thousand horse-power: this human mechanism alone made it possible to raise that colossal structure with the use of only the simplest stone and copper tools—without the aid of such otherwise indispensable machines as the wheel, the wagon, the pulley, the derrick or the winch.

Two things must be noted about this new mechanism, because they identify it through its historic course down to the present. The first is that the organizers of this machine derived their power and authority from a cosmic source. The exactitude in measurement, the abstract mechanical order, the compulsive regularity of this Megamachine sprang directly from astronomical observations and abstract scientific calculations: this inflexible, predictable order, incorporated in the calendar, was then transferred to the regimentation of the human components. By a combination of divine command and ruthless military coercion, a large population was made to endure grinding poverty and forced labour at dull repetitive tasks, in order to ensure "life, prosperity and health" for the divine or semi-divine ruler and his entourage.

The second point is that the grave social defects of the human machine were partly offset by its superb achievements in flood control and grain production, which laid the ground for an enlargement in every area of human culture: in monumental art, in codified law, and in system-

atically pursued and permanently recorded thought. Such order, such collective security and abundance as was achieved in Mesopotamia and Egypt, later in India, China, in the Andean and Mayan cultures, was never surpassed until the Megamachine was re-established in a new form in our own time. But conceptually the machine was already detached from other human functions and purposes than the increase of mechanical power and order: with mordant symbolism, its ultimate products in Egypt were tombs and mummies, while later, in Assyria, the chief testimonial to its efficiency was typically a waste of destroyed cities and poisoned soils.

In a word, what modern economists lately termed the 'Machine Age' had its origin, not in the eighteenth century, but at the very outset of civilization. All its salient characteristics were present from the beginning in both the means and the ends of the collective Megamachine. So Keynes's acute prescription of pyramid building as an essential means of coping with the insensate productivity of a highly mechanized technology, applies both to the earliest manifestations and the present ones; for what is a space rocket but the precise dynamic equivalent, in terms of our present-day theology and cosmology, of the static Egyptian pyramid? Both are devices for securing, at an extravagant cost, a passage to heaven for the favoured few.

Unfortunately, though the labour machine lent itself to vast constructive enterprises, which no small-scale community could even contemplate, much less execute, the most conspicuous result has been achieved through military machines, in colossal acts of destruction and human extermination; acts which monotonously soil the pages of history, from the rape of Sumer to the blasting of Rotterdam and Hiroshima. Sooner or later, I suggest, we must have the courage to ask ourselves: Is this association of inordinate power and productivity with equally inordinate violence and destruction a purely accidental one?

Now the misuse of Megamachines would have proved intolerable had they not also brought genuine benefits to the whole community by raising the ceiling of collective human effort and aspiration. The least of these advantages was the gain in efficiency derived from concentration on rigorously repetitive motions in work, already, indeed, introduced in the grinding and polishing processes of neolithic tool-making. This inured civilized man to long spans of regular work, with higher productive efficiency per unit. But the social by-product of this new discipline was, perhaps, even more significant; for some of the psychological benefits, hitherto confined to religious ritual, were transferred to work. The sterile repetitive tasks imposed by the Megamachine, which in a pathological form we associate with a compulsion neurosis, nevertheless served, like all ritual and restrictive orders, to lessen anxiety and to defend the worker himself from the often demonic promptings of the unconscious, no longer held in check by the traditions and customs of the neolithic village.

In short, mechanization and regimentation, through labour armies, military armies, and ultimately through the derivative modes of industrial and bureaucratic organization, supplemented and increasingly replaced religious ritual as a means of coping with anxiety and promoting psychal stability in mass populations. Orderly, repetitive work provided a daily means of self-control: more pervasive, more effective, more universal than either ritual or law. This hitherto unnoticed psychological contribution was possibly more important than those gains in productive efficiency, which were too often offset by absolute losses in war and conquest. Unfortunately, the ruling classes, which claimed immunity from manual labour, were not subject to this discipline: hence, as the historic record testifies, their disordered fantasies too often found an outlet in reality through destruction and extermination.

Having indicated the beginnings of this process, I must regrettably pass over the actual institutional forces which have been at work during the past five thousand years, and leap, all too suddenly, into the present age, in which the ancient forms of biotechnics are being either suppressed or supplanted, and in which the continued enlargement of the Megamachine itself has become, with increasing compulsiveness, the condition of scientific and technical advance if not the main purpose of human existence. But if the clues I have been attempting to expose prove helpful, many aspects of the scientific and technical transformation of the last three centuries will call for reinterpretation and judicious reconsideration. For, at the very least, we are now bound to explain why the whole process of technical development has become increasingly coercive, totalitarian, and—subjectively speaking—compulsive and irrational.

Before accepting the ultimate translation of all organic processes, biological functions, and human aptitudes into an externally controllable mechanical system, increasingly automatic and self-expanding, it might be well to re-examine the ideological foundations of this whole system, with its concentration on centralized power and external control. We must, in fact, ask ourselves if the probable destination of this system is compatible with the further development of specifically human potentialities.

Consider the alternatives now before us. If man were actually, as present-day theory still supposes, a creature whose use of tools alone played the largest formative part in his development, on what valid grounds do we now propose to strip mankind of the wide variety of autonomous activities historically associated with agriculture and manufacture, leaving the residual mass of workers with the trivial task of watching buttons and dials, and responding to one-way communication and remote control? If man actually owes his intelligence mainly to his tool-using propensities, by what logic do we now take his tools away, so that he will become a functionless, workless being, conditioned to accept only what the Megamachine offers him: an automaton within a larger system of automation, condemned to compulsory consumption, as he was once condemned to compulsory production? What in fact will be left of human life if one function after another is either taken over by the machine, or else genetically suppressed, if not surgically removed?

But if the analysis of human development, in relation to technics sketched out in this article, proves sound, there is an even more fundamental criticism to be made; for we must then go on to questions that would now shift the locus of human activity from the organic environment and the human group to the Megamachine, and eventually reduce all forms of life and culture to those that can be translated into the current system of scientific abstractions, and transferred on a mass basis to machines and electronic apparatus. We are now in a position to question the dubious assumptions that have too long been treated as axioms, for the system of thought on which they are still based, antedated by three centuries anything like the present comprehension—scientific, humanistic and historic—of man's nature and special gifts. From the Pyramid Age to the so-called Nuclear Age, we note, the inventors and controllers of the Megamachine have been haunted by delusions of omniscience and omnipotence; and these delusions are not less irrational now that they have at their disposal all the formidable resources of exact science and a high-energy technology.

The Nuclear Age conception of 'absolute power' and infallible intelligence, exercised by a military-scientific elite, corresponds to the Bronze Age conception of divine kingship; and both belong to the same infantile magico-religious scheme as ritual human sacrifice. Living organisms can use only limited amounts of energy, as living personalities can utilize only limited quantities of knowledge and experience. 'Too much' or 'too little' is equally fatal to organic existence. Even too much abstract

knowledge, insulated from feeling, from moral evaluation, from historic experience, from responsible, purposeful action, can produce a serious unbalance in both the personality and the community. Organisms, societies and human persons are nothing less than delicate devices for regulating energy and putting it at the service of life. To the extent that our Megatechnics ignores these fundamental insights into the nature of organisms and human personalities, it is pro-scientific in its attitude toward the human personality, even when not actively irrational. When the implications of this weakness are taken in, a deliberate large-scale dismantling of the Megamachine in all its institutional forms must surely take place, with a re-distribution of power and authority to smaller units, under direct human control.

If technics is to be brought back again into the service of human culture, the path of advance will lead, not to the further expansion of the Megamachine, but to the development of all those parts of the organic environment and the human personality that have been suppressed in order to magnify the offices of the pure intelligence alone, and therewith to maximize its coercive collective exercise and quantitative productivity. The deliberate expression and fulfilment of human potentialities requires a quite different approach from that bent solely on the control of natural forces, and the modification of human nature in order to facilitate and expand the system of control. We know now that play and sport and ritual and dream-fantasy, no less than organized work, have exercised a formative influence on human culture and even on technics. But make-believe cannot for long be a sufficient substitute for productive work: only when play and work form part of a larger cultural whole, as in Tolstoy's pictures of the mowers in *Anna Karenina*, can the many-sided requirements for full human growth be satisfied.

Instead of liberation from work being the chief contribution of mechanization and automation, I would suggest that liberation for work, for educative, mind-forming work, self-rewarding even on the lowest physiological level, may become the most salutary contribution of a life-centred technology. This may prove an indispensable counter-balance to universal automation: partly by protecting the displaced worker from boredom and suicidal desperation, only temporarily relievable by anaesthetics and sedatives, partly by giving play to constructive impulses, autonomous functions, meaningful activities.

Relieved from abject dependence on the Megamachine, the whole world of biotechnics will at once become open to man; and those parts of his personality that have been crippled or paralysed by insufficient use should again come into play. Automation is indeed the proper end of a purely mechanical system; and in its place, subordinate to other human purposes, automation will serve the human community no less effectively than the reflexes, the hormones, and the autonomic nervous system—Nature's earliest experiment in automation—serve the human body. But autonomy is the proper end of organisms; and further technical development must aim at re-establishing autonomy at every stage of human growth by giving play to every part of the human personality, not merely to those functions which serve the machine.

I realize that in opening up these difficult questions I am not in a position to provide ready-made answers, nor do I suggest that such answers will be easy to fabricate. But it is time that our present wholesale commitment to the machine, which arises largely out of our one-sided interpretation of man's early technical development, should be replaced by a fuller picture of both human nature and the technical *milieu*, as both have evolved together.

THIRD DIMENSION OF MANAGEMENT

By JOHN J. HAYWOOD

Kingston College of Technology, Kingston on Thames

IT is known that management confrontation with problems is a daily event, yet doubt exists as to how, when, or if they are solved. Events generating problems and forces aiding their solution are marshalled both internally and externally with regard to the phenomenon of management. Its activity and involvement can be seen in a three-dimensional perspective. The individual unit, the firm, comprises the first dimension. In this sphere of management, establishment and control of problem-solving aids reflect growth and significance of those internal problems which management recognizes. Accordingly, the firm's individual and peculiar expertise is recruited as a personnel function.

The second dimension of management involvement concerns the group, a nucleus of individual firms. More and different problems are here involved, necessitating a wider and better source of expertise supply, reflecting more diverse problems, different methods of problem-solving, and differing aspects of the same problem found in the first dimension of management.

The third dimension of management involvement concerns industry, both nationally and internationally. The first two dimensions operate within internal constraints. They are introversive approaches to management of enterprise, while the third dimension is essentially extroversive. This outer-directed approach takes cognizance of environmental factors, determined by political, economic, social, and technical forces interacting to produce change, disturbing a given climate within which enterprise may function.

In this dimension, management needs to supplement individual firm and group expertise by use of external supplies of aid to combat those complex problems with which no one enterprise is fully equipped to deal. There is evidence that major problems arise externally, and are more difficult for management to control, a factor lending greater importance to investigation into sources and use made of external aids. Thus a decision was made to investigate and assess both quantitatively and qualitatively sources of external aids, institutional and non-institutional, formal and informal.

The Department of Scientific and Industrial Research financed a twelve-month pilot survey of firms and organizations in the Kingston area of Surrey, and completion was effected in May 1965 (Table 1). No fewer than 362 contact attempts were made, on a random sample basis. The local Ministry of Labour area was used for geographical definition. In all, 241 interviews were obtained, including 25 telephone interviews which were, however, excluded from the survey data. This left data on 189 organizations and 27 aid bodies interviewed in person. There were 68 firms who refused co-operation, 65 who could not be contacted, and 15 offered interviews but were unacceptable, primarily owing to distances involved. Non-contact firms were 18 per cent and refusals 18.75 per cent of the sample, leaving a 63.25 per cent coverage. A representative sample with a cross-section of industries and trades was grouped in conformity with the Standard Industrial Classification. Analysis of refusals of co-operation revealed that, of these, 21 confirmed some use of external aids, while 25 gave no

data, and the remaining 22 showed no common characteristics.

For purposes of analysis, firms were divided into manufacturing, service, and distributive trades, and differentiated over seven variables, *inter alia* with regard to size, type, technology, ownership and management characteristics. External aid bodies were grouped into research and trade associations, management and technical consultants, Government and public bodies, and trade suppliers. Interviewees consisted of managing directors or general managers.

After five revisions a suitable questionnaire *pro forma* report form was developed, while preliminary findings indicated the need for 'depth' interviews with four or five employees to obtain a more reliable guide as to aid usage. Many of the data gained in the investigation could well have been distorted by interviewees attempting to conceal ignorance or to maintain secrecy. Yet confidence was preserved throughout, and no evidence of unreliable data has emerged.

This investigation reveals a recognizable national and international amalgam of external aid-bodies, covering a wide variety of specialist services. This extant market of external aid, both produced and consumed, comprises the third dimension of management. Yet poor communication robs it and Britain of beneficence consequent on full impact. Ignorance by management personnel of where, when, and how to obtain relevant assistance is a functional malady partly due to their inadequate reading, the professional ethic, and indifference of Government agencies.

Nevertheless, our data reveal that advice and assistance were sought from 19 management consultants, 13 technical consultants, 35 professional bodies, 5 international bodies, 31 research associations, 53 Government bodies, and 23 miscellaneous bodies, which represents a minimal use of institutional aids of encouraging magnitude.

In conformity with expectations, it appears that large firms in all sectors used proportionally more external aids than medium- and small-sized firms. The manufacturing sector demonstrates that large firms consumed proportionally more external aids than medium-sized firms, and more absolutely than small firms, the most marked difference being use of management consultants.

A similar trend occurs within the services sector, but a more complex pattern of aid-consumption arises in the

distributive sector. In general, large firms used proportionally more aids, but the incidence of particular aid-consumption varies. There is a marked tendency for greater consumption of research association and technical consultant services by large firms compared with medium-sized firms, and a much greater consumption of research association and management consultant services over small firms.

Certainly large firms can better afford consultants' fees, and may need greater exposure to consultant expertise than smaller firms, which are less prone to complex organizational, production and marketing problems. Consumption of research association services seems more widespread in the manufacturing sector than in either services or distributive sectors. This points to a greater awareness of research benefits, and a more even deployment of internal technocracy in firms engaged in manufacturing activity. Yet it may also reflect a wider gap between the best and average performance firms in both the service and distributive sectors. Increased productivity in the latter sector would contribute much to national economic growth. But size, *per se*, is an indicator neither of effectiveness nor of competence within given areas of enterprise, despite the assumed greater technical expertise and resources available to management. In the science-based industries with dynamic growth-records since the Second World War, some small and medium-sized firms have made contributions to industrial growth out of all proportion to their size. This suggests that they make use of group resources, which are usually available to large organizations.

In the manufacturing sector, subsidiary firms used proportionately more aids than independently owned firms, especially of consultants and research associations. No trend was discernible in service trades, but subsidiaries were greater consumers of management consultant aids than independent firms in the distributive sector. This is encouraging, in that subsidiaries apparently seek the best, rather than the most accessible aids, that is, involvement in second dimension activities is supplemented by third dimension involvement.

In order to assess quantitative use of external aid, interviewees were requested to enumerate and evaluate usage. Informants invariably did not record usage, and though many felt able to evaluate benefits of aid, this was necessarily done in a superficial and subjective fashion. They all found difficulty in isolating the impact of external aid over long or short periods, and they also hesitated to evaluate their firm's efficiency and stability though the latter proved less difficult. Perhaps Prof. J. Johnson's article on the productivity of management consultants¹, regarding a quantitative analysis of the benefits of consultants to management, is indicative of the problems involved here.

Our investigation revealed an unawareness by top management of the extent to which its organization made use of external aid bodies, notably of trade and research associations. Similarly, reasons given for joining these bodies reflect a misunderstanding of the nature of services they can properly supply to management. Furthermore, incorrect use of consultants was not uncommon, for it was not recognized that consultants serve in a therapeutic role, are not magicians and cannot serve as a substitute for good management.

Government agencies are sometimes viewed with contempt and hostility, yet their utility is obvious in exporting activity, and in dissemination of technical knowledge in its customer/supplier relationships. Not least, the Ministry of Technology is responsible for numerous research stations, associations and national laboratories.

This pattern of using the right aids for the wrong reasons, and wrong aids for the right reasons, reflects ignorance and suspicion of external help in problem-solving. It produces a two-fold reaction. Internal resources and expertise may be under-utilized, while industry and

Abbreviations: R.A., research association; T.A., trade association; M.C., management consultant; T.C., technical consultant; Gov., Government and public bodies; Supp., trade suppliers. Ownership: I, independent; S, subsidiaries.

This table only indicates minimum use of external aids, since firms may have used them more than once, in the past two years.

national opportunities fall short of what they could and should be.

External aids are the vehicle of technical and managerial advance via dissemination and propitious use of the latest techniques, systems and, above all, in the moulding of responsive attitudes.

While there is not necessarily a functional relationship between greater alertness and knowledge in management, and its willingness and ability to implement, some relationship does persist. Perhaps the momentum of international competition will stimulate the former and accelerate the latter.

If the impact of external aid consumption on management efficacy was difficult to measure, its incidence proved impracticable to quantify. The role of trade suppliers as an informal, non-institutional aid is probably a more active element in the incidence of aid, than any other. Such aid sources underline the quest for long-term relationships by management as does membership of trade and research associations. There appears to be a significant correlation between size and length of business relationships between suppliers and their customers, and the amount of technical aid received. Again, the earlier pattern of aid consumption is repeated, in that small and medium-sized firms, unable to order in bulk, lose benefits of research and development undertaken by suppliers, especially in diversifying the use of raw materials. In so far as large suppliers use external aids fully and incorporate such help in their products and services, they spread the incidence of third-dimensional involvement to trade buyers. Although analysis of such benefit is problematical, its importance cannot be overlooked.

In this pilot investigation, only eight firms alleged non-usage and non-involvement in external aids to management problem-solving. Analysis of their data and characteristics showed no clear pattern of trends, except that seven were very small, four were old-established independent firms, and only two had modern equipment. Subsequent behavioural characteristics of their top management revealed a comparative abnormality of attitudes for all eight firms, varying from excessive greed for power, to an obsessive desire to save money. The latter found expression in self-design of product packaging, self-advertising and extensive modification of standard machinery products imported from its parent firm. Apparently, management time and effort thus expended was regarded as a cost-free service to the firm.

Again, the impact on management from non-involvement in the third dimension was exceedingly complex and difficult to quantify.

But this survey has shown a different, probably more important, magnitude discernible in terms of the sociological and psychological aspects imbued in management, involved in third-dimensional activities. This is the unquantifiable element of management attitudes, the imagery formed from those impacts on the personality moulded by an environmental intercourse on an industrial, national and international plane. Attitudes are difficult to define and rarely expressed, but are the most vital component of receptiveness to change. This capacity interacts with innovational motivation, which in all functions and levels of management reveals the key to greater productivity. If continual confrontation with aid and involvement in the third dimension of management activity highlights individual shortcomings in knowledge and performance, compared with industry and world leaders, then perhaps the gap between the best and average performances can be narrowed. In this manner, elusive increases in productivity can fall within our grasp. Certainly if every firm increased its productivity by only a small amount, in aggregate national growth objectives would be realized. Enlightened management in leading British firms in all sectors can compete with their foreign rivals, a fact which holds good in the building industry as well as in the chemical and man-made fibres industries.

The third dimension of management in the form of supply and consumption of a variety of specialized services has potentially a powerful part to play in the improvement of industry and national performance. In this connexion, social and psychological aspects of impact and incidence on management imagery are vitally important for Britain's economic future; although not lending themselves to quantitative assessment, they are of such significance that more time and thought should be given to them.

This pilot investigation has many imperfections, but it is a beginning; more research resources are needed in this neglected field of management activity. For, while quantitative method has its place in management science, rigid attitudes of management towards its present role, and future responsibilities and needs, can seriously delay that improvement which is so urgently desired by industry and by Britain as a whole.

¹ Johnson, J., *J. Roy. Stat. Soc.*, 126, II (1963).

STRUCTURES INSIDE A LUNAR CRATER PHOTOGRAPHED BY RANGER VII

By CAPTAIN VERN G. SMALLEY* and LUCIANO B. RONCA

Lunar-Planetary Research Branch, Air Force Cambridge Research Laboratories,
L. G. Hanscom Field, Bedford, Massachusetts

FRAME number 199 of *Ranger VII*'s camera A reveals three structures in a 235-m diameter crater. These features have been the subject of considerable controversy, and their origin is the subject of this article. Fig. 1 is an enlargement of this crater, and the three structures and associated shadows are indicated by numbers and letters, respectively.

The features were analysed in three different ways, using three-dimensional clay models, tonal contour maps, and over-exposed under-developed prints. The first method involved the fabrication of scale models (1 : 1,500) illuminated at an angle of 23° to the horizon, corresponding to the angle of illumination of the lunar surface when the pictures were taken by the spacecraft. Using a Polaroid Land camera, the model was photographed at the *Ranger VII* angle of altitude and azimuth. Then, using a stereoviewer, we simultaneously viewed the model photograph

and the *Ranger VII* photograph, not trying to see a three-dimensional picture, but attempting to simultaneously compare the two photographs. In this manner one is able to pay very close attention to even small differences in the fine details in both photographs.

It was found that the shadows in this feature are so related that the placement of one shadow greatly influences the position of others. Changing the elevation of any one feature in the model results in a change of shadows which in turn results in a change of other elevations which in turn results in the change of other shadows, etc. By making innumerable modifications in our models, we made the photographs of the model match the *Ranger VII* photograph. To obtain an independent appraisal of this feature, we obtained the assistance of a professional artist, Mr. Emilius Ciampa, a sculptor trained in the investigation of light-and-shadow effects. Mr. Ciampa's model was identical in major outline to ours, strengthening

* At present at the Cosmic Radiation Branch.

the validity of the final interpretation, a stereo photograph of which is shown in Fig. 2.

The second phase of our investigation involved a tonal contour study. Using a first-generation 35-mm master negative of Frame A-199, we obtained a micro-analyser trace of the 235-m crater. The effective spot size was 11.2μ , and the traces were spaced 25μ apart. The output of the analyser was then digitized, and the results were plotted in a two-dimensional array and contoured (Fig. 3).

The third method of analysis undertaken was that which involved over-exposed and under-developed prints (Fig. 4). We found that by long exposures (5–6 min duration at

$f/5.6$) of high contrast paper (Kodak F/5), and by pulling the print from the developer prematurely, we were able to assess degrees of darkness of shadows which are normally completely black. The results thus obtained from these three investigations were analysed for clues which may suggest a probable origin.

A number of conclusions were obtained from this investigation:

(1) All three structures, Nos. 1, 2 and 3, are illuminated by primary sunlight. The possibility of at least one of the structures being illuminated by reflected light was discarded after an examination of scale-models which

Fig. 1. Magnified detail of photograph 199 of *Ranger VII*'s camera A. Positive structures 1, 2 and 3 and shadows A, B, C, D, and E are indicated

were fabricated by the professional sculptor. In order to have reflected lighting, a steep cliff, shown as a dashed line in Fig. 1, would have to be the reflecting surface. From geometric considerations, it is difficult to explain reflected light to any one of the three structures and to maintain shadows *A* and *B* (Fig. 1) so extremely dark. Further, it is unlikely that the material of this structure could have a sufficient albedo to reflect the large amount of light necessary. Our conclusion is that all three structures are illuminated by direct lighting.

(2) The smooth portion of the 235-m crater floor is of lighter tone than the surroundings. It is impossible to reproduce the light tone of the crater floor without either tipping it strongly toward the light source or increasing the albedo. As the crater floor is unlikely to be steeply inclined, an increase in albedo is necessary.

(3) A lengthy examination of the results revealed that there were several steep slopes associated with the three structures. The northern side of structure 3 is very steep,

and an indication of this is seen in Fig. 1. There is no projection west of shadow *C*, but this shadow is seen to partially lie north of structure 3. This can only be explained by having a trench at that point. In other words, the north side of structure 3 is steep enough to have the terrain immediately north of it in shadow. This was easily verified in the three-dimensional analysis.

The southern slope of structure 3 is likewise steep. Shadow *A* is reasonably symmetrical about an east-west line which passes through the eastern-most point of that shadow. We argue that the slope south of structure 3 can only be steep, in view of the symmetry of shadow *A* and the close proximity of the dark portion of shadow *A*. A slight slope could not explain the sudden difference in quantity of reflected light, nor is it consistent with the geometry shown in the three-dimensional model study.

The west sides of structures 1 and 2 are thought to be steep, because gentle slopes could not account for the darkness of shadows *A* and *B*. The north and south sides of structure 2 are likewise thought to be steep. We experimented with various slopes and geometries, and found that only very steep slopes could reasonably account for the shape of shadow *A*.

We concluded, therefore, that very steep slopes, with more than 70° of inclination, exist on the north and south sides of structure 3, steep slopes with inclination of 45° – 60° exist on the east sides of structures 1, 2 and probably on the north and south sides of structure 2.

(4) The steep slopes in some cases do not stop at what would normally be the basin of the 235-m crater, but appear to be related to topographic lows, which are lower than the crater basin. These lows are also suggested by the over-exposed under-developed prints, which indicated uncommonly dark zones. The intensity of the darkness suggests that there exist topographic lows in these shadow zones, and that they are lower than the undisturbed floor of the crater. The darkness of a shadow is not linearly proportional to the depth of the low; but, other things being equal, the greater the depth within the shadow, the greater will be the intensity of darkness of the shadows. Considering this, and the topography of the terrain adjacent to the shadows, we conclude that shadows *A* and *B* traverse terrain which is lower than the adjacent terrain. This is supported also by the fact that, in order to place properly the eastern border of shadow *B* in the three-dimensional analysis, the terrain immediately to the east of this border had to slope slightly downward (see broad arrow in Fig. 1) towards structure 1.

(5) We were able to suggest a reasonable depth of the 235-m crater as a result of the three-dimensional model examined. We found the depth at the centre of the basin to be of the order of 40–50 m. Structures 1, 2 and 3 have heights above the basin of approximately 30, 20 and 20 m, respectively. The minimum volume of structure 1, that is, the portion which appears to rise above the floor of the crater, was determined by cutting that portion of the clay away with a sharp knife, rolling it into a ball, and measuring the diameter. The minimum volume was thus found to be 68,000 cubic metres.

(6) We also found that what was depicted as a circular summit crater on structure 1 in the Aeronautical Chart

Fig. 2. Stereo pair of clay model

Fig. 3. Tonal contour map. The cross-hatched areas indicate shadows; areas with hachures indicate bright areas

Fig. 4. Over-exposed under-developed print, showing the extremely dark areas, which are interpreted as being topographic lows

and Information Center's lunar chart, RLC 4, is in reality a U-shaped valley, extending downward to the north-east, and, rather than occurring at the summit, it occurs half-way down the gentle slope of that structure.

We therefore conclude that all three structures, 1, 2 and 3, are illuminated by primary sunlight; that the three structures are not the rims of, or are not due to, several minor craters in the 235-m crater; that associated with each of the three structures there is at least one steep slope; and that there are topographic lows within this crater that are lower than the crater floor. With this quantity of the topography known, we shall now proceed to interpret this information and suggest what we believe a reasonable origin.

Conceivably, the structures in the main crater could have one of the following origins:

- (1) The structures are pre-crater buried highs which are exposed during the formation of the crater.
- (2) The structures are contemporaneous or pene-contemporaneous with the crater. That is, they are the remnants of the projectile which caused the crater or they are chunks of local material dislodged by the impact.
- (3) The structures are post-crater. (a) The structures are the result of primary, secondary or tertiary impact in a pre-existing crater. (b) The structures were caused by

an endogenous process in a pre-existing crater.

It is unlikely that the structures are pre-crater, because the topographic lows, deeper than the floor of the main crater, and the steep slopes of the structures are unlikely to have survived an impact severe enough to have created a 235-m crater.

The second possibility, that the structures are contemporaneous or pene-contemporaneous with the main crater, also seems unlikely. Whether the structures tumbled down the slope of the crater immediately after its formation, or are the remnants of an impacting body, it would be surprising if they retained their large dimensions and steep slopes after undergoing the shock of either tumbling or deceleration. Lunar surface material is supposed to have low cohesive strength at this scale¹ and the angle of repose is not affected by the low lunar gravity².

Another argument against these structures being contemporaneous or pene-contemporaneous is based on the occurrence of other similar features. The mechanisms which we have discussed up to this point should be common to all other craters. We find it strange that the occurrence of structures in the basins of other similar craters is so rare. A reasonable conclusion is that the structures did not form, or were not placed, at the time of the formation of the crater, but at a later date. Thus, we are led to consider post-crater processes.

If we assume the structures to be post-crater, they could have been formed by either of two mechanisms: impact on a pre-existing crater or endogenous activity in a pre-existing crater.

The main objection to impact on a pre-existing crater is again the steepness of the walls of the structures. Whatever the origin of the 235-m crater (meteoritic impact, volcanism or collapse), it is likely that the material was brecciated. Impact on an already brecciated area should not have resulted in the stacking of material in three neat piles with nearly vertical walls.

Finally, endogenous activity is the last mechanism. There are several known volcanic processes on the Earth which would result in vertical walls and tall masses located near topographic lows, bearing in mind that on the Moon there may be other processes not known on Earth. It is not necessary to call for deep-rooted volcanism, as the structures could have been caused by a 'rootless activity centre', that is, a pocket where the gas content of a mare flow was unusually high. Ignimbrite flows on Earth are known to have such phenomena³.

It is also possible that the structures could be the result of deposition of minerals due to water percolating through the surface layer; the lows might be due to violent release of volatiles.

The structures inside a 235-m crater have therefore been carefully analysed. The conclusion that they are the result of an impact appeared unlikely due to the presence of steep-walled structures and topographic lows. The endogenous theory is favoured, and it is suggested that mechanisms such as rootless volcanic activity, real volcanic activity, or venting volatiles are responsible for this feature.

NEWS and VIEWS

The Royal Society of London:

Medal Awards

THE following awards of medals have been made by the President and the Council of the Royal Society: *The Copley Medal*, to Prof. A. L. Hodgkin, Foulerton research professor of the Royal Society (working in the Physiological Laboratory, Cambridge), for his discovery of the mechanism of excitation and impulse conduction in nerve, and his outstanding leadership in the development of neurophysiology; *The Davy Medal*, to Prof. H. W. Thompson, professor of chemistry in the Physical Chemistry Laboratory, Oxford, for his distinguished contributions to infra-red spectroscopy and its application to chemical problems; *The Hughes Medal*, to Prof. D. H. Wilkinson, professor of experimental physics in the University of Oxford, for his distinguished experimental and theoretical investigation in nuclear structure and high-energy physics.

Chemical Pathology at Guy's Hospital Medical School :
Prof. Sydney Cohen

DR. S. COHEN, reader in immunology in St. Mary's Hospital Medical School, has been appointed to the chair of chemical pathology at Guy's Hospital Medical School, in succession to Prof. R. H. S. Thompson, who has been appointed to the Courtauld chair of biochemistry in the Middlesex Hospital Medical School (*Nature*, 205, 1053; 1965). Dr. Cohen, a graduate of the Universities of Witwatersrand and London, spent a year at the Post-graduate Medical School at Hammersmith in 1947-48 and a year as Nuffield Dominion Fellow at the National Institute for Medical Research, 1954-55, so that he was familiar with London before he decided to come here permanently and to accept an appointment to the scientific staff of the National Institute in 1957. Dr. Cohen had been interested for some time in protein metabolism, and in collaboration with Dr. A. S. McFarlane he continued this work using experimental animals, but he also organized a Metabolic Unit for the Medical Research Council at the Archway Hospital so that this work could be extended to human subjects. He made important contributions during this period, particularly to knowledge of the metabolism of the immunoglobulin, and not surprisingly this aroused his interest in the rapidly developing field of immunology. In 1960 he became reader in the newly formed Department of Immunology at St. Mary's Hospital Medical School, where he played a large part in getting the teaching and research under way, and he soon established an international reputation in what quickly became a highly competitive field of research. Although still primarily a laboratory worker, he increased his clinical interests and he introduced several diagnostic techniques which were of great value to the hospital. This combination of clinical interest with high attainment in laboratory work is not very common in English medicine and there is no doubt that Guy's Hospital has been fortunate in finding in Dr. Cohen a person well equipped to make the most of the wider opportunities which this new position offers him.

Pharmaceutical Technology in the University of Strathclyde:
Prof. P. H. Elworthy

DR. P. H. ELWORTHY, senior lecturer in pharmaceutical chemistry in the Department of Pharmacy in the University of Strathclyde, has been appointed to the new chair of pharmaceutical technology at the University from January 1. Dr. Elworthy was educated at Mercers' School, Holborn, London, and at the School of Pharmacy, University of London, where he graduated with honours

in 1953, and where he was awarded a Ph.D. degree for research in physical chemistry in 1956. After a period on the staff of the School of Pharmacy, London, he became a lecturer in the Department of Pharmacy in the then Royal College of Science and Technology, Glasgow in 1959. He was appointed senior lecturer in pharmaceutical chemistry at the University in 1964. In 1966 he spent three months' leave of absence from the University in various pharmaceutical companies studying the application of physical chemistry to problems of pharmaceutical formulation. Six months' leave of absence granted during 1964, enabled him to work at the University of Southern California as a visiting lecturer on some properties of detergent solutions. Dr. Elworthy's research interests lie in investigations of the mode of action of detergents as emulsifying and suspending agents in pharmaceutical preparations, in producing models of the cell membrane, and in the relation of shape of certain drug molecules to their biological activity. His published work has resulted in the award of a D.Sc. degree this year.

Transport and Technology

THE debate in the House of Commons on the Queen's Speech on November 16 was concerned mainly with matters of transport and, to a lesser extent, of technology. The Minister of Transport, Mr. T. Fraser, in referring to the studies in the co-ordination of transport which were in hand, emphasized his belief that very great social benefit would arise from reversing the present trend of putting traffic now carried by road on to the railways apart from the full utilization of our investment in our railway system. He emphasized also that we could not continue to waste our resources on unproductive services but in dealing with closures he said he had not looked merely at the loss incurred. He hoped shortly to announce an arrangement under which British Railways and British Road Services will jointly operate a new parcels and sundries service throughout the country, each contributing the part for which it was best fitted. He was seeking further measures of freight co-ordination by which the railways would undertake the longer hauls for which they were best suited, and he was in touch with all main transport authorities in an endeavour to improve rail-road co-ordination for passengers. He also added, in reply to a question, that the practicability of the proposals for road pricing in the Sneed report was being intensively investigated. Apart from some questioning of the establishment of the Ministry of Technology and of the failure to set up the Industrial Research and Development Authority recommended by the Trend Committee, there was little mention of technology, as distinct from transport, in the debate.

Management Training in the Civil Service

IN a written answer in the House of Commons on November 12, the Financial Secretary to the Treasury Mr. N. MacDermot, stated that he had appointed a working party, with Mr. S. P. Osmond as chairman, to consider the training needs for middle and higher management in the Civil Service and to submit recommendations on the length, content and organization of such training taking account of the long-term future of the Centre for Administrative Studies and the desirability or otherwise of setting up a Civil Service Staff College. The members include Prof. Jean Blondel, Prof. D. C. Hague and Prof. E. A. G. Robinson, with R. Haynes, R. Hayward, C. D. E. Keeling, R. B. M. King, W. McCall, J. Parsons, C. H. Sisson, L. Williams, G. P. Hampshire and I. G. Gilber (secretary).

Regional Economic Development

IN a written answer in the House of Commons on November 18, the Joint Under-Secretary of State for Economic Affairs, Mr. W. Rodgers, stated that the National Institute for Economic and Social Research had been commissioned to carry out a three-year project under the direction, from the late summer or early autumn of 1966, of Prof. A. J. Brown, "to build up a theoretical and empirical framework for the analysis of regional economic development and the consideration of regional policy in the United Kingdom especially in relation to problems of national economic development". He had also recently discussed the priorities for regional research with representatives of regional planning councils, who were now considering which projects they would regard as most urgent. The Department was also prepared to consider proposals for projects on regional economic matters from those working in the field.

British Productivity Council

IN support of a proposed National Campaign for Quality and Reliability, plans for designating a Quality and Reliability Year (QRY), October 1966–September 1967, were announced on October 29 by the British Productivity Council and the National Council for Quality and Reliability. Details of the scheme are available from the British Productivity Council, Vintry House, Queen Street Place, London, E.C.4. The campaign is to be launched throughout Britain and its object is to emphasize the benefits of quality with built-in reliability, and the ways and means of achieving it. The turnover of British manufacturing industry in 1964 was £10,114 million. It has been shown that adoption of the methods which will be advocated during QRY can produce savings in the range of 1.5–5 per cent of gross turnover, while maintaining or raising product quality. Even on the lowest percentage, savings of £150 million a year should be well within the grasp of manufacturing industry. The technique which will be the *raison d'être* of the campaign, and which, as is rightly pointed out, must begin at the design stage of the product, involves: reduction of costs; reducing scrap and re-work; considerably reducing Britain's import bill for raw materials; ensuring that delivery dates are kept or improved; increasing earnings, not by harder work but by increased efficiency and "doing it right first time"; and giving more customer satisfaction by consistency of product. The Quality and Reliability Year is already assured of widespread support by representative industrial, national and professional bodies in Britain. Its patron is H.R.H. Prince Philip, Duke of Edinburgh, who, in the course of a message sent to the organizing council, commented that a good reputation for well-designed goods or components, fit for the purpose, which do not fail or break down, is the criterion for certain success. A bad reputation is a very costly luxury which Britain cannot afford.

Overseas Development Institute

THE Overseas Development Institute, set up in 1960, is an independent non-Government body aiming to ensure wise action in the field of overseas development. It is financed by grants from the Ford Foundation, British foundations, and by donations from British industrial and commercial concerns. Its declared functions are: to provide a centre for co-ordination of studies on development problems; to direct studies of its own; to be a forum for all concerned with development problems to facilitate contacts, discussions, and sharing of ideas; to spread information collected as widely as possible among those concerned with development problems; and to keep the urgency of such problems before the public and responsible authorities. An instance of one of the most recent activities of the Institute is provided by a publication entitled *British Private Investment in East Africa*,

by D. J. Morgan (Pp. 62. London: The Overseas Development Institute, Ltd., 1965. 7s. 6d.). The argument is that private investment overseas is a matter of controversy. It is sometimes blamed for balance of payment difficulties; the rate of such investment in developing countries is on the decline; Africa, in particular, has been affected by this changing pattern. For this reason, East Africa was chosen as a special area for study. This pamphlet is, in effect, a report of a survey and a conference. The survey was undertaken by the Institute in conjunction with the Federation of British Industries and the Dulverton Trust, and involved sending a questionnaire to 1,500 British firms concerned in East Africa; the replies are analysed and, at a conference held during June 1965, various obstacles to investment in that area were discussed and some vital economic questions posed. Among the latter are: Is East Africa a growth area? Are profit margins high enough to attract British investment? How important are tax and other concessions? What are the political risks? All these questions are examined in this pamphlet and to a large extent answered, but the conclusions reached still leave unsolved the basic problem of declining investment in East African enterprises, unless combined action by the African Governments concerned, the British Government, and equally important, British industry itself, materializes.

Science Papers of the Victorian Era

THE great majority of John Dalton's manuscripts were presented to the Manchester Literary and Philosophical Society in 1864 by his literary executor, William Charles Henry. More than three-quarters of the original collection was destroyed during the Second World War and many of the surviving items are in such a charred and brittle condition that their future preservation is problematical; careful separation and sorting of the charred sheets was a lengthy but necessary preliminary to the actual cataloguing of the collection. Subsequent to this partial destruction, the Society has received various gifts, including a collection originally presented to Dalton Hall, a hall of residence of the University of Manchester. These manuscripts in the possession of the Society have now been microfilmed, occupying four spools of a total length of 340 ft., of which printed matter occupies about 320 ft. The material consists of lecture notes, papers, notebooks, meteorological records, correspondence, domestic accounts and some rare printed items such as lecture syllabuses. The microfilm is available either in negative or in positive form; the former is judged to be more legible. The Society has also made available a microfilm of letters from J. P. Joule and John Mercer to Lyon Playfair dealing with scientific topics during 1841–49. The film consists of about 16 ft. of correspondence from Joule and 16 ft. of correspondence from Mercer.

Laboratory Photochemical Reactor

A PHOTOCHEMICAL reactor suitable for small-scale photochemical research in universities and industrial research laboratories is now available from Engelhard Hanovia Lamps (Slough, Bucks.). This welcome addition to their range of ultra-violet equipment was shown as a prototype at the Oxford International Congress of Photo-Biology in June 1964 and is now available from stock. The reactor consists of a three-necked glass flask fitted with standard ground glass sockets. One of these receives a clear quartz thimble which in turn holds a smaller quartz thimble containing the ultra-violet lamp. There is provision for water-cooling of the space between the inner and outer thimbles, and for nitrogen flushing of the lamp chamber to eliminate ozone. Use of high-purity synthetic quartz in the thimbles ensures good ultra-violet transmission characteristics. Two lamps are available for the reactor, a 100-W medium pressure lamp emitting a range of radiations from 185 to 366 mμ and a 2-W cold-cathode

low-pressure lamp emitting mainly at 185 m μ and 254 m μ . Both lamps have synthetic quartz envelopes. The reactor will undoubtedly be valuable for physical chemistry research as well as biological work, and the cone and socket arrangement makes it suitable for use also in the study of reactions in the gaseous phase. By circulating oxygen or air around the lamp it could, of course, be used as an ozone generator.

Alaskan Mammals

A USEFUL brochure entitled *The Distribution of Alaskan Mammals*, by R. H. Manville and S. P. Young, has been published by the U.S. Bureau of Sport Fisheries and Wildlife (United States Department of the Interior: Fish and Wildlife Service. Bureau of Sport Fisheries and Wildlife. Circular No. 211. Pp. iv+74. Washington, D.C.: Government Printing Office, 1965. 50 cents). A map showing the distribution within the State is given for each species, together with notes on the complete range of the species, its habitat, the races found in Alaska, and on related species. A black-and-white drawing illustrates each species competently; the scraper-board figures greatly exceed in effect those in pen and ink; that of the porcupine, *Erethizon dorsatum*, and especially that of the bearded seal, *Erignathus barbatus*, are splendid. The Cetacea are not treated in detail but are given an overall note and a list of recorded species. The introductory matter includes a short article on the distribution of Alaskan mammals, another on the mammalian fauna in general, and a list of 102 species in systematic order. The rapid opening up of the State to travel and tourism, and the establishment of the University and other centres of scientific activity, give great opportunities for an intensified study of Alaskan mammals, for which this publication will provide a valuable foundation.

Conservation of the Bee Orchis

RARE bee orchises (*Ophrys apifera*) were discovered on the Dykes of the Avebury Stone Circle, Wiltshire, during July 1965, by one of the custodians of the Office of Works, Mr. Hulbert, and the curator of the Museum, Mr. H. M. V. Young, who immediately alerted the headmistress of the parochial school, and her assistants and caretaker, all keen naturalists. The teachers found that the plants were flowering in the same spot in which they had appeared eight years ago, widely scattered over an area of 300 square yards. Seventeen were counted in bloom, and investigation showed that there had been at least twenty-two. Of the five known casualties, two had been picked by local adults and three were found discarded, probably by a coach party who may have carried some others away. Only nine Avebury people knew of the bee orchids and they agreed to conserve them if possible. Photographs were taken and further counts were made by the headmistress, who thinks one more was picked during the next week. Fourteen days from the first discovery, only one in the fruiting stage was seen, and this had well-formed seed pods. Bad weather and long grass prevented a prolonged search, but it is hoped that a few more remained to set seed. This small effort at conservation was prompted by a lecture on the Nature Conservancy Trust given by the Countess of Radnor to the Wiltshire Rural Studies Association. Further information can be obtained from Miss E. Dampier-Child, School House, Avebury, Wiltshire.

The International Commission on Radiological Protection

THE following have been elected officers and members of the International Commission on Radiological Protection for the period 1965-69: *Chairman*, Dr. E. E. Pochin (United Kingdom); *Vice-Chairman*, Dr. C. G. Stewart (Canada); *Council*, Prof. L. Bugnard (France),

Prof. O. Hug (Germany), Dr. H. Jammet (France), Prof. A. A. Letavet (U.S.S.R.), Prof. B. Lindell (Sweden), Dr. J. F. Loutit (United Kingdom), Dr. K. Z. Morgan (United States), Dr. H. B. Newcombe (Canada), Dr. C. C. Powell (United States), Dr. L. S. Taylor (United States) and Prof. B. Windeyer (United Kingdom); *Chairman Emeritus*, Prof. R. M. Sievert (Sweden); *Scientific Secretary*, Dr. F. D. Sowby (Canada). The Commission's secretariat is at Clifton Avenue, Sutton, Surrey, England.

The National Institute of Sciences of India

THE following have been elected members of the Council of the National Institute of Sciences of India for 1966: *President*, Dr. V. R. Khanolkar; *Vice-President*, Dr. Atma Ram and Dr. S. Bhagavantam; *Treasurer*, Prof. R. C. Majumdar; *Foreign Secretary*, Prof. B. F. Seshachar; *Secretaries*, Prof. F. C. Auluck and Dr. N. K. Panikkar; *Editor of Publications*, Prof. P. Maheshwari; *Members of Council*, Sri S. Basu, Prof. P. N. Bhadur, Prof. P. L. Bhatnagar, Prof. R. N. Chakravarti, Prof. N. F. Dhar, Dr. K. R. Dixit, Dr. T. R. Govindachari, Dr. A. C. Jhingran, Dr. M. S. Krishnan, Prof. T. S. Mahabale, Prof. K. C. Mukherji, Dr. K. R. Nair, Dr. B. P. Pal, Dr. R. E. Pal, Prof. T. R. Seshadri, Prof. S. M. Sircar, Prof. Venkateswarlu, Prof. P. N. Wahi and Dr. H. J. Bhabha (past president, *ex-officio*).

The Year Book of the National Institute of Sciences of India, 1964 (Pp. 133. New Delhi: National Institute of Sciences of India, 1965), includes, besides an account of the foundation of the Institute and the calendar for 1964, list of the Council senior office staff, of Fellows, of the members of committees, and of representatives on other organizations. The rules and regulations of the Institute are also included as well as lists of the Institute's medals, lectures and publications.

University and College News:

Cambridge

THE following have been elected to fellowships at Churchill College: *Title A*, Dr. I. T. Drummond (mathematics); *Title B*, Dr. B. B. Roberts.

Edinburg

THE following lecturers have been appointed: J. B. Penman (animal health); Dr. J. S. McKinley (biochemistry).

University College of Swansea

THE following lecturers have been appointed: Dr. R. C. V. Macario and D. Bell (electrical engineering).

Announcements

A SYMPOSIUM on "CNS-Drugs" will be held at the Regional Research Laboratory, Hyderabad, during January 24-30. Further information can be obtained from Dr. P. B. Sattur, Regional Research Laboratory, Hyderabad 9.

A SYMPOSIUM on "Regulation of the Antibody Response" will be held in Toronto during January 20-22. Further information can be obtained from Dr. B. C. Braden, Subdivision of Immunochemistry, Division of Biological Research, O.C.I., 500 Sherbourne Street, Toronto 5.

A ONE-DAY symposium on "Engineering the World's Airport Passenger Terminals" will be held at the Institution of Civil Engineers, London, on January 25. Further information can be obtained from the Secretary, Institution of Civil Engineers, Great George Street, London S.W.1.

A ONE-DAY symposium on "Food Safety", organized by the Luton College of Technology and the Institute of Biology, will be held in the College on January 26. Further information can be obtained from Dr. F. C. Webber, Luton College of Technology, Park Square, Luton, Bedfordshire.

CENTENARY OF THE QUEKETT MICROSCOPICAL CLUB

THE Quekett Microscopical Club celebrated its centenary with an exhibition at the Central Hall, Westminster, during October 8-9. This club, named in commemoration of Prof. John T. Quekett of the Royal College of Surgeons (1815-1861), has fostered the interests of microscopists by holding meetings and promoting field work throughout the past hundred years.

Foremost among the exhibits were a number of family relics loaned by Captain Charles Quekett, the great-grandson of John Quekett. Several examples of Quekett's work, including the manuscript of the *Catalogue of the Histological Collection* and a small selection of his microscopical preparations, were displayed by the Royal College of Surgeons. A fine display of microscopes made before 1865 was shown by Dr. H. Heywood. Mr. E. P. Herlihy's exhibit of portable microscopes, many of which dated from the past century, emphasized the great part these models have played in the history of the Club by facilitating the demonstration of microscopical preparations at the meetings. The historical display also included numerous examples of instruments and accessories designed or made by past members, and the work of Richard Beck, Andrew and Thomas Ross, Powell and Lealand, J. W. Stephenson, F. H. Wenham and Julius Rheinberg was well represented. Dr. Savile Bradbury contributed a special display devoted to E. M. Nelson—one of the Club's most famous members; and we were reminded that Ernst Abbe had been an honorary member of many years standing.

The rest of the space in the main hall was devoted to members' and guests' individual exhibits. The light reflexion in the eye of the spur dogfish was shown to be due to the presence of guanine crystals in the layer known as the silvery tapetum. Two exhibits of electron microscopy in the investigation of neurophysiology and neuropathology were shown by Drs. Bradbury, Harris and Salmon. Prof. Booth from Saskatoon demonstrated his Kerr-effect microscope for the visualization of magnetic domains. Dr. Gahan gave a demonstration of the cytochemistry of chromosomes. These were but a few of the

exhibits, which also included beautiful mounts of diatoms and mosses among the 'showpieces'.

The versatility and skill of members was shown by various pieces of apparatus for aiding microscopical techniques. These included various kinds of magazine slide-carriers, a home-constructed mounting cabinet incorporating an electrically driven ringing turntable, a simple but very effective mechanical finger for aiding the arranging and mounting of diatoms and similar minute objects, and a tube-length corrector mounted in the body-work of a microscope. Three members showed microscopes made by themselves. An original display showed the use of paper-sculptures to illustrate microscopic and natural-history specimens. A number of excellent drawings and paintings of entomological and botanical subjects were shown by Miss Dorothy Fitchew.

A programme of films included a 16-mm sound colour film on modern freeze-sectioning by the Pathology Department of the Royal College of Surgeons, and another, by a member, dealing with crystal growth. Sessions of micro-projection on a home-built machine by Mr. H. S. Henderson aroused admiration.

A trade exhibition was held in the smaller hall and many firms displayed their latest models of microscopes and photomicrographic apparatus. Many teaching aids for microscopy were on view, and a display of live *Daphnia* and *Volvox* projected by Flatters and Garnett evoked much interest. Dissection microscopes and equipment were shown in addition to knife-sharpening machines and an automatic staining apparatus.

It is estimated that about a thousand people attended the exhibition. These included a number of young people from schools and technical colleges, and it is anticipated that many will, in the future, want to join this flourishing club. The general opinion seemed to be that the centenary of the Club that commemorates that foremost microscopist of the past century, Prof. John T. Quekett, had been worthily celebrated.

G. J. CUNNINGHAM

TEACHING IN THE HISTORY AND PHILOSOPHY OF SCIENCE

By DR. W. MAYS

Department of Philosophy, University of Manchester

IN 1960 a questionnaire was sent out to British and Commonwealth universities to determine what teaching was being done in the history and philosophy of science¹. As it was felt that some of the information was now out of date, it was decided in April 1965 to make a further survey, restricting it this time to British and Irish universities. Since 1960 a number of new universities have been established; there have also been numerous debates on the so-called 'two cultures'. It was, therefore, of interest to see whether these factors had had any significant effect on the development of the subject. In all 34 replies were received. These covered the greater part of the universities to which circulars were sent, and they can be said to give a representative picture of the state of teaching in the subject at the moment.

What general impression does one gain when one looks over the replies? First, it seems clear that there

have been no dramatic developments. The past five years have been a period of consolidation rather than rapid advance. There has, it is true, been the establishment of two new departments in the history of science and technology. One at the Imperial College of Science and Technology, the other at the Manchester College of Science and Technology. A Department of the History and Philosophy of Science has also been set up at Queen's University, Belfast.

The consolidation has perhaps been greatest in those institutions where independent appointments have been made. Where the teaching has been largely on a voluntary basis, there has in some cases been an actual decrease in activity, either due to the interested member of the staff leaving the institution or getting disheartened. As was noted in the 1960 survey, one of the reasons why the subject has not grown commensurately with its educational

value is that it usually had to be a subsidiary enterprise of one or two interested people, who have not always been able to muster sufficient support for the subject.

Since the last survey there has been an increase in appointments, and a number of them have been in departments of philosophy. It would seem that philosophers are now taking a greater interest in the subject, at least in the philosophy of science, than are scientists and historians. This seems to reverse the trend noted previously¹, when scientists and historians appeared to be showing a greater interest. Some philosophers even complained that they found scientists not always willing to co-operate with them.

Although philosophers are now supporting the subject by the creation of appointments in their departments, there still is, however, something to be said in favour of separate departments of the history and philosophy of science. In some philosophy departments there could be a tendency to undervalue the history of science, thus overlooking that historical techniques can provide an intellectual discipline of a high order. In departments of history or history of science, there may be a tendency to neglect the philosophical aspects of the subject, and to regard them as speculative. Both aspects seem necessary, if one is to develop a balanced perspective of the nature of science.

In view of the debates on the 'two cultures' it is surprising that there has not been greater interest in the history and philosophy of science in universities. One would have thought that to offer courses in it was one way of getting arts students to learn something about the aims and methods of science, and of bridging the alleged gap between the 'two cultures'. As students can now take history and philosophy of science as a subject for the General Certificate of Education, one would have assumed that an increased provision of courses at the university-level might have stimulated more of them to take it at school.

It was noted in the 1960 survey that interest in the subject seemed dependent on the size of the university, date of foundation, and the priority given to cultural questions *vis-à-vis* bread-and-butter ones. To this one must add that the subject has a chance to grow in universities where departmental boundaries are flexible and inter-faculty co-operation exists. In universities with excessive departmentalism, inter-disciplinary subjects may be faced with difficulties. Teachers of established courses may feel that with a limited number of students to go round, the development of the history and philosophy of science can only be at the expense of their own subject.

At Oxford and Cambridge there has been a steady increase in activity. Oxford is developing the subject at a number of levels, and forging links with historians and philosophers. The history of science can, for example, be taken as a special subject by third-year historians. Classes and lectures of postgraduate standard go on throughout the year. These are taken by candidates for the B.Phil. and the diploma in the history and philosophy of science.

Cambridge has now replaced the certificate in the history and philosophy of science, which could be taken as a post-Part I, by a Part II of the natural sciences tripos (general honours) in which there is a choice of four papers from a panel of six, three of which emphasize the historical side and three the philosophical side. In addition the subject can be taken as an option in Part I of the natural sciences tripos. It is also planned to have an option in the projected M.Phil.

So far as the newer universities are concerned, Sussex seems to be the only one at which appointments have been made, and it teaches the history as well as the philosophy of science. York expects to have philosophy of science available as an optional paper from 1966 onwards, to be taken by undergraduates reading for the B.A. in a combined honours course. Lancaster hopes to

provide an optional undergraduate course in the philosophy of science and another in the philosophy of mathematics. The physics department there is providing a course in the basic ideas of physics for students majoring in the arts and sciences.

Warwick intends to put on a common course for all freshmen to deal with the nature and methods of the humanities and the natural and social sciences, and it is hoped to develop philosophy of science as a special option. East Anglia plans to give an optional course in the philosophy of science in the School of Mathematics and Physics in 1967; Kent hopes to have an option for philosophy and science students in 1965, and is also starting courses in science and religion and the methodology of science. As only a limited range of subjects can be taught in the newer universities, the older-established studies would seem to stand a better chance of being included in the syllabus. However, the philosophy departments of some of these universities intend to develop teaching in the philosophy of science and to appoint staff to teach it.

Among the other universities, the sub-department in the University of Leeds is very active. The subject is taught to undergraduates in the Faculties of Arts, Science and Technology, and with five staff members it can cover a range of topics. Both Belfast and Dublin gave courses in which the historical and philosophical aspects were equally stressed. Durham has appointments in both the history of science and the philosophy of science, and plans to integrate more closely the teaching of these subjects. In Wales, both Bangor and Aberystwyth have courses in the philosophy of science and the foundations of mathematics. Leicester gives a one-year course in the history of science, which can be taken by students in any faculty or year, and it also provides a course in the philosophy of science.

In London there are now three main university centres: the London School of Economics, University College and the Imperial College of Science and Technology. The latter, which is a new department, will give undergraduate courses and provide research facilities for the Ph.D. and M.Sc. degrees. In Scotland, Aberdeen shows some expansion in staff and courses; it also runs classes in conjunction with the Medical Faculty.

It is interesting to note that the courses offered by Cambridge and Dublin include topics in what might be called the 'history and philosophy of psychology', for example, the mind-body relationship and the unconscious. Furthermore, in view of the development of sociology in British universities in recent years, it would probably be worth while to have more courses in the history and philosophy of the social sciences. One gains the perhaps mistaken impression that the subject is sometimes rather narrowly interpreted in terms of the physical sciences. It might well be the case that the history and philosophy of the biological and social sciences would not only be more acceptable to mathematically unsophisticated arts students, but also more profitable educationally for them.

In conclusion, progress certainly seems to have been made during the past five years, though perhaps it has not been spectacular. Taken in conjunction with developments in the colleges of advanced technology (we know, for example, of one new department and a number of new appointments here) progress in the teaching of the subject is appreciably greater than would appear from our survey. It is probable that the increased activity in the colleges of advanced technology may feed back again into the universities and stimulate further interest.

Mention in detail cannot be made here of the other universities which provide, or intend to provide, teaching in the subject. These include Birmingham, Bristol, Exeter, Keele, Manchester, Newcastle, Nottingham, Liverpool, Reading, St. Andrews, Sheffield, Southampton and Swansea.

¹ Mays, W., *Nature*, 189, 971 (1961).

EDUCATION AND APPLICATION OF THE MATERIALS SCIENTIST

It has recently been said¹ that in an economy which is no better than its best materials, there is no lack of employment for the materials scientist. The Materials Science Club, composed as it is of members from a variety of disciplines, has endeavoured to direct attention to the factors that enable the country to benefit by the most advantageous utilization of the materials scientist. Consideration has already been given to collaboration between industrial and academic bodies², and it was a natural development to consider "The Education and Application of the Materials Scientist" as a main topic during the third Banbury Conference of the Club during October 1-3.

This was also the occasion of the presentation of the Club's A. A. Griffith Medal to the first recipient, Dr. A. H. Cottrell. The A. A. Griffith Medal will be awarded annually by the Materials Science Club to a British scientist who has made a distinguished contribution to the study of materials science or technology. In making the presentation, the Club president, Mr. L. Holliday, paid tribute to the generosity of Rolls-Royce, who had financed the fabrication of the medal die. Briefly sketching the career of A. A. Griffith, who is to be considered a pioneer in the field of materials science because of his work on crack propagation and the strength of materials, Mr. Holliday recalled that it was in 1917 that Griffith was presented with his first medal. Between 1914 and 1939 Griffith had a distinguished career at the Royal Aircraft Establishment, Farnborough, then moving to Rolls-Royce, Ltd., where during 1939 until 1960 he was engaged on advanced research, particularly in the field of vertical take-off aircraft. In 1941 he was elected to the Royal Society.

Turning to the distinguished career of Dr. Cottrell³, Mr. Holliday said that it was in 1954 that he was awarded his first medal, the Rosenhain Medal, and was elected a Fellow of the Royal Society in 1955. In research, Dr. Cottrell has been concerned with the plastic deformation of metal crystals, with creep and fracture phenomena, and more recently with whisker and composite materials. This year, Dr. Cottrell left the Department of Metallurgy at Cambridge, where he was Goldsmith professor, to take up the post of deputy chief scientific adviser to the Ministry of Defence. In presenting the Medal, the president referred to the fact that it was now forty-five years after the publication of the Griffith theory of crack propagation in brittle materials, and added by way of anticipation that he felt that by the year 2010 there would be somewhere an A. H. Cottrell Medal.

In thanking the president and the Club, Dr. Cottrell expressed his pleasure at being associated with A. A. Griffith in this way, since he had long been his admirer, particularly with regard to the theory of fracture and crack propagation. He considered the original treatment elegant and the power of the method profound. It was with regret that he was unable to deliver a lecture at the conference, but the pressures of his recent appointment made it necessary to defer this to a future meeting of the Club.

The opening lecture was given by Prof. D. D. Eley, on 'Adhesion'; he spoke immediately after the annual Club dinner. After briefly tracing the events which led to his involvement in this subject, which can conveniently be studied as a branch of surface chemistry, attention was

then directed to the classification of the process of joint formation: (1) wetting of the solid surface; (2) setting of the adhesive; (3) deformation to release any stress set up in the previous step. Consideration was given to the thermodynamic work of adhesion and to the measurement of heats of immersion by highly accurate calorimetric methods. In order to assess joint strength it is necessary to devise some form of standard joint, which has resulted in the Napkin ring test, and the various techniques involved were described. The penetration of the liquid adhesive into the porous solid and the nature of the adherend are of prime importance, and a variety of treatments to give an increase in surface area were considered. In determining the heats of wetting to this surface a variety of the problems involved were indicated and in particular the time to complete the research work was constantly emphasized. Prof. Eley indicated that this was the type of research that was perhaps only possible in a university, because the cost would be a severe drain on the financial resources of any industrial concern. Finally, the strengths of the molecular forces involved were considered. At the conclusion of the lecture a series of exhibits were passed to the audience which illustrated a variety of the uses of the modern adhesive, and in particular their use in the aircraft industry.

In the four papers which were next presented, a pattern for the future training of the scientist competent in the materials field gradually emerged. The first, by Mr. D. M. Cunningham (Woolwich Polytechnic), on 'Prospects in Materials Science', presented the results of a statistical survey, the objects of which were: (a) to test attitudes and opinions about this recently defined study; (b) closely connected with the first object—to obtain some idea of the kind of training thought most suitable for future materials scientists; (c) to make some kind of quantitative estimate of the number of people engaged in materials science, together with some growth projection into the future.

Mr. Cunningham explained the manner in which the survey had been conducted, together with the various tests which had been applied to establish randomness of samples and confidence in the results. It would appear that there is substantial agreement that materials science is a combination of 'pure' and 'applied' science and that physics and chemistry should provide the basis for undergraduate courses. The study of materials science as such should, in general, be reserved for the postgraduate level. It was of interest to note that approximately 5 per cent of pure scientists and the same proportion of mechanical, electrical and chemical engineers claim that their work directly encompasses materials science. Thus by 1968 there could be about 10,000 scientists and engineers effectively concerned in materials science. About 4,000 of these might well be chemists and/or physicists and about 5,000 engineers, the remainder being metallurgists, mathematicians, etc. There is a possibility that the demand for scientific workers in the field of materials science may well rise more rapidly than the demand for all scientists and technologists. This demand will have to be met, during the next three years, from the present resources since the output of materials scientists trained as such is likely to be small. Mr. Cunningham emphasized that the foregoing conclusions are rather pre-

curiously based on relatively small samples and that the estimates of the total numbers in particular should be regarded as approximate.

The part played by the schools in equipping candidates at advanced level with the necessary educational background is of fundamental importance in the structure of further-educational courses. Dr. J. E. Spice (Winchester), in his paper "Physical Science as an 'A'-Level Course", described the progress that has been made in this science teaching project which is sponsored by the Nuffield Foundation. It was Dr. Spice's view that physical science could be a more satisfying and exciting 'A'-level subject than physics or chemistry separately. It could be taken together with either mathematics or biology, so that it would be possible to satisfy university entrance requirements for courses in science, medicine and technology with two 'A'-level passes at a high enough level instead of three as at present. This would allow the better sixth-formers to take a third, unrelated subject at 'A'-level, for example, economics or a modern language. Perhaps as important, it would also enable the choice of a university course to be deferred until later in a student's school career than at present.

The Nuffield Science Teaching Project has now set up a Joint Committee for the Physical Sciences at 'A'-level, which is co-ordinating the work of three separate groups. These groups are producing Nuffield-style 'A'-level courses in physics, in chemistry, and in physical science, and it is hoped that trials will begin in selected schools in September 1966.

The physical science course would have a small number of key concepts (such as energy, and the structure of matter) as unifying themes. At the same time, it would introduce pupils to all the topics and techniques which entrants to honours courses in physics and chemistry should know. It is also hoped to introduce the pupil to experiments so designed that he is taught to find things out for himself and become less dependent on memorized facts.

Prof. R. W. Cahn next spoke about the teaching of materials science at the University of Sussex. He began by explaining the system of schools of study which was used for all teaching in the new University. Students who were going to specialize in materials science took preliminary courses in structure and properties of matter as a principal subject (an atomistic approach to physics and chemistry), mathematics and either chemistry or further mathematics. Thereafter, materials science would be taken as a major subject in either the School of Applied Sciences or the School of Molecular Sciences.

In the School of Applied Sciences, materials science courses were accompanied by a variety of courses in engineering topics such as electronics, mechanics of fluids, automatic control theory, etc. The planned materials science course included first a detailed course devoted to the electrical and magnetic properties of matter with detailed emphasis on semi-conductors and ferro-magnetic materials and to the mechanical properties and the physical factors determining them. Consideration is also given to the various techniques for preparing and refining materials and assessing their properties. The materials specialists also have an introduction to physical metallurgy with special emphasis on nucleation and transformation, and of course crystallographic and diffraction techniques. A great deal of emphasis was to be placed on laboratory experiments, and Prof. Cahn explained his philosophy about such experiments and emphasized their importance as a means of "costing out fear" of unfamiliar techniques while also developing dexterity and an awareness of the source of error.

It was also possible to major in materials science in the School of Molecular Sciences, and here the emphasis would be scientific rather than of an engineering nature. The programme included lectures on quantum mechanics, crystal chemistry, molecular spectroscopy and topics in

inorganic chemistry, all given by physicists or chemists. A materials scientist would be responsible for a detailed course in crystallography and defect theory with special attention to dislocations, and there would also be a course surveying the methods of mechanical and physical characteristics of materials. Students would, of course, attend a basic course on electrical and magnetic properties jointly with students of the School of Applied Sciences. In conclusion, Prof. Cahn said that it was too soon to say which of the two alternative ways of preparing a materials science specialist would prove to be more successful and more popular, and it might well be that one or other of these would prove to be so superior to the other that only one approach would eventually be offered.

The title "Management of Materials Science Research" enabled the next contributor, Dr. F. J. P. Clark (U.K. Atomic Energy Authority), to convince the Club that it should have a half-day's conference on management. He pointed out that in the majority of industrial concerns the expenditure on people attending management conferences is relatively much less than on technical conferences. It has been maintained by Holloman, among others, that good management is so important that it matters little whether the principles involved are applied to research and development or, for example, running a pickle factory. If management principles are as important as this example suggests, then more attention should be paid to them.

Examples were then given of some of the primary functions of a research manager. To begin with, a distinction was made between three levels of management: first, the most senior level at which general objectives are determined; secondly, the executive level at which a decision is made on how these should be achieved; and thirdly, the responsibility of the day-to-day organization of the work. Dr. Clark then particularly directed his remarks towards the second category in management. The primary job of a research manager is to define objectives, and the advantages of clearly defined objectives are numerous. Two were mentioned in particular: (1) diffuseness in research is prevented; (2) clear definition of objectives can provide opportunities for scientists to exercise responsible freedom in their research. In an example it was shown that scientists, given freedom to involve themselves in divergent research, in fact converged their research on objectives if those objectives had been sufficiently well defined. Another function of a manager is to provide the organizational and intellectual environment in which the objectives can be obtained. This means removing potential sources of frustration inherent in poor organization. On the intellectual side, this means an appreciation of the fact that the best results are obtained by a sharing of the thinking that leads to decisions. The speaker finally argued that there was definite experimental evidence supporting the contention that the efficiency of scientists as scientists was increased by their participation in administrative jobs, perhaps to the extent of a quarter of their total time.

The first of four papers on specific materials and problems in the materials field was given by Dr. H. Fessler (University of Nottingham) and was entitled "Some Problems in Strain Measurement of Non-Linear Materials". Dr. Fessler discussed the way in which the mechanical engineer, to utilize fully the capacity of a material, wishes to know the stress to failure within very fine limits. In considering the phenomena of confined plastic deformation and shape of mechanical components, reference was made to the unexpected failure of materials. The plastic-elastic distribution can only be obtained by direct measurement of the strain of the material in the component form; several techniques, such as point measurement, field methods, brittle coatings, Moiré fringe patterns and the birefringence of photo-elastic materials are all at present being used.

The photo-elastic method is of particular importance to the mechanical engineer, and Dr. Fessler made a plea for some effort to be directed towards the improvement of the materials at present available for this technique.

Factors which influence the choice of such a material may be listed as follows:

The model constructed in the photo-elastic material must reproduce the strain in the original.

The model must be loaded so as to imitate the structural component. Good optical sensitivity is required, it being desirable to increase the amount of birefringence for each given strain at least ten-fold.

The material should be chemically and mechanically stable, and preferably not very hygroscopic and should exhibit negligible volume change on setting. It should be as homogeneous and as isotropic as the material being copied.

The material should be castable in blocks by a curing reaction which should not be excessively exothermic since this could produce an undesirable initial birefringence, and the glass/rubber transition temperature should not be far removed from laboratory temperatures.

A Poisson's ratio of about one-third would be most convenient.

The part played by the epoxy resins as photo-elastic materials was then indicated, particularly in the light of the previous suggestions.

The examination of photo-processes is of obvious relevance to photoactive materials such as photographic emulsions, photosynthetic plants, photo-conductive electronic and laser devices. In his paper "Photoprocesses in Materials" Dr. D. J. Morantz (Woolwich Polytechnic) also emphasized the important information concerning the microstructure of materials that may be obtained by the study of these processes, three examples of photoprocesses being discussed:

(a) *The production of metastable excited states.* This phenomenon, which is well known, enables the inversion of the population of electronic states in photoactive material. This inversion is normally removed by spontaneous emission; alternatively, in a suitable optical cavity, inversion enables the onset of laser action.

(b) *Photochromism.* This refers to the production of a reversible colour change on exposure of a substance to light. The mechanism may involve a metastable state, a geometrical isomer or, more usually, a reversible chemical change. Such phenomena may be used for the photosensitized control of light transmission (for example, cryptocyanin in Q-switched lasers), and photochromism has been proposed for use in memory devices for computers. Although use of such devices is unlikely with present technology, Dr. Morantz proposed that, on a molecular level, interaction between photoactive chromophores in polymer chains may in the future provide feasible systems.

(c) *Photo-ionization.* The photo-ejection of electrons on irradiation may be followed by reaction in a liquid or gas medium. In a solid the electrons may be trapped and may subsequently be induced to recombine with the positive ions by thermal or radiational activation of the traps. The ionized material may be coloured and the act of recombination may result in luminescence. Dr. Morantz described work in his laboratory on the investigation of luminescence intensities, life-times and spectra, from which evidence is available that each of these parameters is dependent on the nature of the solid material which provides the trapping sites.

In concluding, correlations were discussed with the materials requirements of the previous speaker, when it was generally agreed that the use of photo-stimulated emission may lead to a more sensitive method.

A picture of present-day technology in the light of developments in solid-state physics was given by Dr. H. G. Howell (British Plaster Board Holdings, Ltd.) in

his paper, "Some Material Thoughts on Gypsum". In introducing the topic, Dr. Howell described the physical chemistry underlying the changes involved in going from rock gypsum to hemihydrate and then to dihydrate, with particular reference to crystal structure of the species, and the influence of hydrogen bonds on the crystal cleavage planes. In the case of hemihydrate it is found that properties are exhibited which are sensitive to the method of preparation, in spite of materials being identical with regard to their X-ray structures. The need for controlling the set of α -plaster and the part played by crystal size and habit in this operation are closely connected, and the elimination of voids becomes important with regard to realization of ultimate mechanical strength. It was interesting to learn that plaster of Paris is as strong as cement and could be its rival as a structural material except for its unfortunate solubility, and that many other hydrates form equally attractive structural materials.

In his paper, "Unorthodox Structural Materials", Mr. N. J. Parratt (E.R.D.E., Waltham Abbey) examined the strength of traditional materials, where the mean elastic bond strain at failure may be between 0.1 and 1.0 per cent and the tensile strength is therefore about that fraction of the Young's modulus. Since most structures are intended to be light in weight, as a first approximation Young's modulus divided by specific gravity may be used as a comparative criterion. The common structural materials have $E/s.g.$ close to 3.9×10^6 lb./in.², but this figure may be improved on by some high-specific modulus materials such as aluminium nitride, boron, carbon whiskers, silicon carbide and particularly silicon nitride, which has the figure 17×10^6 lb./in.². Mr. Parratt then explained how these materials may be exploited in the form of whisker crystals as reinforcing agents. To be of general use, an economic process for the mass production of whiskers would be desirable, and the developments towards this from laboratory experiments to semi-scale plant were described.

Delegates at the conference were able to visit a special exhibition of materials dealing with "Materials Science Technology at Aldermaston", which was organized under the direction of Dr. D. Deverell, of the Atomic Weapons Research Establishment. The range of work in materials carried out at Aldermaston is very wide and it is impossible to do more than mention some of these most interesting exhibits: glass-fibre reinforced concrete—to solve the problem of designing a non-magnetic clamping system to withstand repulsive forces between collector plates of a megajoule discharge bank; optical materials—special techniques have been developed to obtain high-grade optical properties in stainless-steel mirrors for high-speed cameras and in special light-weight aluminium mirrors; composite materials—reinforced metal matrices using whisker crystals, particularly with aligned fibres, the apparatus and product of each technique being displayed; joining—welding of less common metals, a variety of uranium and beryllium joints were shown, together with an example of a special technique, the electron beam welding of titanium-backed polythene.

In addition to these specialized subjects were examples of general materials research in the fields of, for example, adhesives, foam plastics, cellular rubbers, encapsulants, surface coatings and isostatic pressing. Since U.K. Atomic Energy Authority staff were in attendance at the stands, delegates were afforded the welcome opportunity to discuss in detail the various materials and techniques in the exhibition.

It would now seem opportune to direct attention to next year's Banbury Conference, when some consideration will be given to "The Selection of Engineering Materials", and to add that suggested contributions may now be submitted.

EVIDENCE FOR STRUCTURES RESEMBLING CRYSTALLINE CARBONS AT THE ACTIVE CENTRE OF ENZYMES

By DR. E. D. WACHSMUTH

Institut für Biochemie, Universität Frankfurt am Main, Germany

THE bondings between the even-numbered members of a homologous series of aliphatic acids, amines and amino-acids are relatively stronger than those between the odd-numbered ones. This can be illustrated by the alternating melting points of such a series of compounds. Parallel to the melting points there is also an alternation in the adsorption of a series of hydrocarbons¹ and of a series of aliphatic acids^{2,3} on porous carbon. Thus non-crystalline structures are also apparently most stable when even-numbered chains of carbon atoms are adsorbed. Therefore an investigation of the effects of inhibitors and substrates containing hydrocarbon side-chains of different lengths should cast light on the steric configuration around the active centre of enzymes. This influence on an enzyme has been interpreted until now only as a hydrophobic interaction between enzyme and substrate. For example, of all the amino-acids existing in Nature, derivatives of leucine are very easily hydrolysed by the leucineamino-peptidase described by Smith and Spackman⁴ because of its most hydrophobic side-chain. In the case of alcohol-dehydrogenase, an increase in the size of substrate, or branching in the side-chain of the substrate, results in reduced activity⁵⁻⁹. These two types of enzymes were thus selected for detailed investigations to determine whether the molecular form in addition to the hydrophobic character of the substrate is important for interaction with the enzymes.

Inhibition experiments with pure aminopeptidase of pig kidney show that the longer is the side-chain of aliphatic acids, amines and amides, then the greater is the inhibition of hydrolysis of the leucine derivatives¹⁰. In contrast to the classical leucineaminopeptidase⁴ the aminopeptidase used in this work was prepared by a method¹¹ which avoided the use of denaturing agents. Since the inhibitions are competitive, the longer-chain inhibitors seem to be better able to replace the substrate on the hydrophobic binding site on the enzyme¹⁰. Such a competitive displacement is no longer possible when the substrate lacks a hydrophobic side-chain as is the case with glycine. Thus, when glycine derivatives were used as substrates¹⁰ the inhibition was un-competitive and showed an alternating pattern depending on the length of the side-chain of the inhibitor, as demonstrated in Fig. 1 for aliphatic acids. The even-numbered derivatives had relatively higher K_M and V'_{max} values than the odd ones and paralleled the

melting points of those inhibitors. As for liver alcohol dehydrogenase, aliphatic acids and amides are also known to have an alternating effect on the enzymatic reaction but these results were previously thought to be due to experimental errors¹² (Fig. 1). Fig. 2 shows that the K'_M values of a series of amino-acids used as inhibitors for the enzymatic hydrolysis of glycine *p*-nitranilide by amino peptidase also closely parallel the melting points.

Fig. 2. Hydrolysis of glycine *p*-nitranilide by aminopeptidase measured in the presence of 0.01 M solutions of amino-acids. The Michaelis constants (molar) and maximal rates of hydrolysis (at 37°) in the presence of amino-acids are designated K'_M and V'_{max} and were measured from Lineweaver and Burk plots¹⁴. + - - +, melting points of amino-acids

The best criteria for judging the degree of interaction between an enzyme and its substrate are the V_{max} values. They represent directly the dissociation of the enzyme-substrate-complex, whereas the interpretation of K_M values is more complicated. Fig. 3 shows these constants for the hydrolysis of various amino-acid amides by aminopeptidase. The curve demonstrates that the even-numbered amino-acid amides are relatively more rapidly hydrolysed than the odd-numbered ones. The K_M and V_{max} values for alcoholdehydrogenase of liver (Fig. 4) have been measured and show similar variations according to the length of the hydrocarbon side-chain. The results in Fig. 5 illustrate the existence of similar relations for different alcohols used as substrates for yeast alcoholdehydrogenase. The oscillating variation of both the melting points and the V_{max} values with liver alcoholdehydrogenase ceases with alcohols longer than pentanol^{8,9}.

As for aminopeptidase of pig kidney, alcoholdehydrogenase of yeast and beef liver, a change in the length of the side-chain of the substrate results in relatively better substrates if the hydrocarbon side-chain is even-numbered than if it is odd-numbered. Very similar variations were found in the inhibitors. This parallels the melting points and the adsorption on porous carbon of all hydrocarbon derivatives tested. Since the melting points are decomposition points, they illustrate the adsorption of hydrocarbons on one another and analogously on porous carbon. Thus, it must be concluded, there should be a structure on the enzyme surface, which resembles that of a crystalline carbon.

By comparing aminopeptidase with the alcoholdehydrogenases it is apparent that both the adsorption of the substrates by the enzymes and the maximum rates of

Fig. 1. Inhibition of enzymatic action by aliphatic acids. AP: V'_{max} of aminopeptidase in the presence of 0.5 M inhibitor. ADH: K_1 of liver alcoholdehydrogenase¹². F: melting points of aliphatic acids

hydrolysis vary in the same way with the length of the hydrocarbon side-chain (for aminopeptidase without carboxyl group, Figs. 3 and 4). As for alcoholdehydrogenases the hydroxyl group should be expected to be both recognized and specifically bound, whereas in the case of aminopeptidase we have proved the amino group and the carbonyl residue of the *N*-terminal amino-acid to be bound by the enzyme¹⁰. In this scheme the hydrocarbon side-chains serve as orientating groups which may be relatively favourably (C-even) or unfavourably (C-odd) bound by the enzyme.

The optimum type of side-chain is a straight chain of hydrocarbon. The introduction of an ether bridge instead of a $-\text{CH}_2-$ group into the substrate increases K_M and reduces V_{\max} (methyl- or ethyl-cellosolve, Table 1). Branched side-chains result in the same effect, as illustrated in Table 1 for alcoholdehydrogenase and in Fig. 3 for aminopeptidase (valine).

From the ratio of K_M to V_{\max} it may be possible to gain an idea of the size of the active centre itself. For example, both the aminopeptidase of pig kidney and the alcoholdehydrogenase of yeast exhibit their highest turnover numbers with substrates containing a 2-carbon side-chain. One explanation could be that these 2-carbon

Fig. 5. The constants for the dehydrogenation of various straight-chain alcohols by yeast alcoholdehydrogenase measured from Lineweaver and Burk plots¹⁴. For experimental conditions see ref. 13

substrates offer the optimal orientation and thus the least steric hindrance for the conformational change of the enzyme-substrate-complex which occurs during the enzymatic reaction. This orientating effect is lacking in the case of the single carbon atom substrates, glycine and methanol. Bound substrates with more than two carbons in the backbone of the molecule present a greater steric hindrance to conformational change. In the case of liver alcoholdehydrogenase this hindrance is not apparent unless there are more than four carbon atoms in the substrate molecule^{6,9}.

Table 1. KINETIC CONSTANTS OF YEAST ALCOHOLDEHYDROGENASE WITH VARIOUS ALCOHOLS (For experimental conditions see ref. 13)

Alcohol	K_M (molar) $\times 10^{-2}$	V_{\max} (in % of ethanol) dehydrogenation
<i>n</i> -propanol	2.2	29
iso-propanol	20.8	3.6
<i>n</i> -butanol	1.5	21
sec.-butanol	18.2	3.6
tert.-butanol	—	0
<i>n</i> -butanol	1.5	21
methyl-cellosolve	5.2	0.5
<i>n</i> -amylalcohol	1.3	3
ethyl-cellosolve	10.4	0.5

These results, as a whole, show—analogueous to the melting points and the adsorption effects on porous carbon—that there is a high degree of order on the surface of these enzymes in the neighbourhood of the active centre which closely resembles the structure of crystalline carbon. If the orientation of the hydrocarbon side-chain starts from the tightly bound reactive part of the substrate molecule, the side-chain can either increase (even-numbered) or decrease (odd-numbered) the hydrophobic interactions between the enzyme binding site and a substrate or an inhibitor.

THE WOLF CREEK IRON METEORITE

By PROF. S. R. TAYLOR

Department of Geophysics and Geochemistry, Australian National University, Canberra

THE discovery of the crater due to meteorite impact near Wolf Creek, Western Australia, was first reported by Reeves and Chalmers¹. Guppy and Matheson² gave a fuller description. The Wolf Creek crater (Fig. 1) is situated at long. 127° 48' E. and lat. 19° 11' S. (co-

ordinates of south-east sector of rim) 2,800 m. east of Wolf Creek in the East Kimberley District, Western Australia. The nearest town is Halls Creek, 66 miles north of the crater. The crater diameter (rim to rim) varies between 870 and 950 m (ref. 3). This size is

Fig. 1. Aerial view of Wolf Creek meteorite crater, looking north

Fig. 2. Fragments of Wolf Creek iron meteorite showing size and form. Note the many angular fragments

exceeded only by the Arizona meteorite crater (Canyon Diablo meteorite) among craters with associated meteoritic material⁴.

Guppy and Matheson², Cassidy⁵, LaPaz⁶ and McCall⁷ have described the nickel-rich oxidized meteoritic material which was moderately abundant, but has now been extensively collected. No typical metallic meteorite specimens have been reported previously, although Guppy and Matheson² recovered trace amounts of metallic iron from the oxidized material, and LaPaz⁶ reported streaks and granules of metal in two large (120 and 125 kg) oxidized masses.

The purpose of this article is to report the discovery of fragments of a typical iron meteorite near the crater. In June 1965, Dr. P. Kolbe and Mr. E. H. Pedersen, of this Department, mapped Wolf Creek crater as part of a survey of Australian meteorite craters. In August 1965, Mrs. J. Moyle of Carranya Station, about 3 miles south-west of the crater, forwarded a small piece of iron meteorite found by Andy Timperley and a companion who are employed at the station. Following identification of the

fragment, the locality was visited by Mr. E. H. Pedersen and myself. On August 30 and subsequent days, 1,343 g were collected.

The fragments were found lying on the surface among small pebbles, overlying a calcareous clay soil without pebbles or meteorite fragments. The ground is partly covered by spinifex (*Triodia* sp.) but is otherwise barren. The fragments were found mainly in an elliptical area with axes of 30 and 20 m, 3,900 m south-west (235°) of the crater. The distance west from the creek on this bearing is 1,100 m. Other fragments were found about 100 m to the west and a large fragment (70 g) about 500 m west of the creek. Much of this area was traversed using a mine detector, but no large buried masses were located. A low ridge with a calcareous capping rises about 100 m north of the principal locality. Small sinkholes, not to be confused with impact features, have developed near the edge of the scarp facing the creek.

Fig. 2 shows the size-range collected, and the typical forms of the fragments. The largest piece (top left) weighs 72.6 g and the four smallest (bottom right) weigh 0.114, 0.114, 0.269 and 0.128 g respectively. The surface of the fragments is heavily oxidized. Their shape commonly is oriented parallel to the Widmanstätten structure developed parallel to octahedral planes. There is no definite evidence of modification by fusion of the surface, and the regular outlines, with occasional projecting spikes, are interpreted as due to secondary fragmentation of a larger mass, cleaving along the octahedral planes.

Fig. 3 shows polished and etched surfaces of four specimens, displaying well-developed Widmanstätten structure with alternating broad lamellae of kamacite (nickel-poor body-centred cubic or α -iron) and taenite (nickel-rich

Fig. 3. Polished and etched sections showing Widmanstätten structure

face-centred cubic or γ -iron). The average width of the kamacite lamellae is about 0.9 mm. This falls within the range of kamacite band-widths (0.5–1.5 mm) of the medium octahedrite class of iron meteorites⁴. Chemical analysis gives a nickel content of 8.6 and 0.4 per cent of cobalt, rather close to the average of all iron meteorites reported by Mason⁴, and confirming the classification as a medium octahedrite.

INITIATION OF CHAIN REACTION UNDER AN ULTRASONIC WAVE EFFECT

By PROF. I. E. ELPINER, A. V. SOKOLSKAYA and M. A. MARGULIS

Institute of Biological Physics, Academy of Sciences of the U.S.S.R., Moscow

CHEMICAL processes which proceed in an ultrasonic wave field are mainly conditioned by cavitation phenomenon. According to existing theories, gases, molecules of water and other compounds, penetrating into a cavitation bubble, undergo ionization or activation as a result of large electrical tensions¹ or large pressures². The oxidation and reduction reactions usually observed in sonicated aqueous media are related to the appearance of ions and short- or long-living radicals. To a great extent, the character of these reactions depends on the nature of the gas which saturates the sonicated aqueous solution. Moreover, it transpires that the character of ultrasonic reactions also depends on the nature of rare (noble) gases that are present in solution. Thus, oxidation processes proceed in an ultrasonic wave field not only in presence of oxygen but also in its absence if the sonicated solution has been previously saturated with argon or krypton (but not with helium)³⁻⁶. A suggestion was made that krypton or argon, excited in an ultrasonic field, 'catalyse' the process of splitting water molecules with the result that activated OH-radicals are formed which participate in oxidative reactions.

These observations revealed new possibilities of the control over ultrasonic chemical processes and suggested

a way of investigating the elementary phenomena which form the basis of ultrasonic reactions. The problem of the intensifying of the reactions remains the urgent one.

We present here data which show that atoms and radicals, initiating reactions with large-quantum yield, can be formed by means of an ultrasonic wave effect. By 'initiating reactions' we mean the initiation of chain reactions, or, more precisely, the possibility of obtaining active particles which are necessary for chain formation. It has been suggested that for some admixtures (initiators), dissociation in the cavitation bubble with the concomitant formation of atoms or radicals provides the beginning of chain reactions under the influence of ultrasonic waves. This has now been confirmed by the following experiment.

We investigated the possibility of initiating a stereoisomerization effect in ethylene 'raw' compounds (ethylene-1,2-dicarboxylic acid and its dimethyl ether) when placed in an ultrasonic wave field.

It should be noted that the isomerization reaction of maleic acid with the concomitant formation of fumaric acid proceeds under the influence of ultra-violet light or visible light in the presence of an initiator—a small amount of bromine. This process has the characteristic

features of a chain reaction which usually can be represented as the following scheme⁷:

and so on . . .

It can be seen that the primary reaction here is the appearance of $\text{Br} \cdot$ atoms. Bromine atoms react with *cis*-isomer molecule with the formation of free radicals:

which is transformed into more stable *trans*-isomer.

In darkness, isomerization of maleic acid into fumaric acid does not occur under the conditions mentioned even after 18 h (see Table 1). Later some experiments on sonication of the investigated mixtures were carried out in darkness.

In our work, ultrasonic oscillations having a frequency of 860 kc/s were used; 33 per cent aqueous solutions of maleic acid were sonicated in the presence of a small amount of bromine (0.0079 mole of Br_2 was added per mole of maleic acid). The sonicated solutions were saturated previously with oxygen, hydrogen, helium, argon or nitrogen.

Control of the course of the reaction is possible, owing to the fact that the fumaric acid formed, unlike maleic acid, is poorly soluble in water and precipitates as white needle-like crystals. Quantitative analyses of fumaric acid were carried out by the weighing technique.

As Table 1 shows, isomerization of maleic acid with the formation of fumaric acid proceeds at comparatively short exposures to ultrasonic waves. (The melting-point of the product obtained is 286° C, which corresponds to that of fumaric acid.) At the same time it appears that the reaction is inhibited if the reaction mixture has been previously saturated with oxygen. In the presence of the latter the reaction proceeds more slowly than in the presence of a rare gas.

Table 1. THE AMOUNT OF FUMARIC ACID, PRODUCED ACCORDING TO THE NATURE OF THE GAS, SATURATING THE AQUEOUS SOLUTION OF MALEIC ACID SONICATED IN DARKNESS

Five ml. of aqueous solution containing maleic acid (33 per cent) and 0.5 ml. of bromine water were sonicated under a frequency of 860 kc/s and intensity 12 W/cm²

Time of sonication (min)	Amount of fumaric acid produced on sonication in presence of:							
	Ar		He		O ₂		H ₂	
	g	%	g	%	g	%	g	%
5	0.1983	11.9	0.1472	8.8	0	—	0.1606	9.6
10	0.2034	12.2	0.1812	10.9	0	—	0.1383	8.3
15	0.2818	16.9	0.2161	13.0	0	—	0.2462	14.8
20	—	—	0.1294	7.8	0	—	—	—
35	—	—	—	—	0.043	2.6	—	—
20*	0	0	—	—	—	—	0	—
100*	0	0	—	—	—	—	0	—
18 h†	0	0	—	—	—	—	—	—

* Sonication was carried out in the absence of bromine.

† The solution studied was maintained in darkness and not sonicated.

Similar results were obtained when aqueous solutions of dimethyl ether of maleic acid were subjected to ultrasonic waves in the presence of catalytic amounts of bromine. Precipitation of small crystals of the dimethyl ether of fumaric acid occurred 2–3 min after the sonication commenced in darkness (after recrystallization m.p. was 151° C, which is characteristic of this compound).

The appearance of atomic bromine, which initiates the given chain reaction, apparently proceeds in the cavitation bubble. If we take into account the fact that the duration of life of the $\text{Br} \cdot$ is of the order of 10^{-7} – 10^{-8} sec, that is, smaller than the period of applied ultrasound or smaller than the duration of life of the cavitation bubble, the interaction between bromine atom and *cis*-isomer molecule should be considered to occur on the bubble-fluid interface. On the given interface the molecules of oxygen, penetrating into the cavitation bubble, halt the chain reaction which has begun, and form intermediate peroxide-inactive compounds with reaction products^{3,4}.

Later it was found that by ultrasonic chemical transformations some bromine-containing aliphatic compounds release atomic bromine which also initiates the chain reaction of isomerization of maleic acid into fumaric acid. The experiments were carried out on 1,2-dibromoethane ($\text{C}_2\text{H}_4\text{Br}_2$) and *n*-hexyl bromide ($\text{C}_6\text{H}_{11}\text{Br}$); 5 ml. of a 33 per cent aqueous solution of maleic acid plus 0.5 ml. of water, saturated at 60°–70° C with dibromoethane or *n*-hexyl bromide, were treated with ultrasonic waves.

The results of the investigation using dibromoethane are given in Table 2.

Table 2. THE AMOUNT OF FUMARIC ACID, PRODUCED ACCORDING TO THE NATURE OF THE GAS, SATURATING THE AQUEOUS SOLUTION OF 33 PER CENT MALEIC ACID SONICATED IN DARKNESS

Five ml. aqueous solution plus 0.5 ml. of water saturated with $\text{C}_2\text{H}_4\text{Br}_2$ were sonicated under a frequency of 860 kc/s and intensity 12 W/cm²

Gas, present during sonication	Time of sonication (min)	Amount of produced fumaric acid (g)
Hydrogen	75	0
Hydrogen	120	0
Argon	40	0.072
Argon	60	0.057
Oxygen	30	0.055
Air	60	0.050

In this case, it also seems that the bromine atoms are formed in a cavitation bubble where dibromo-ethane (or *n*-hexyl bromide) penetrates owing to the high elasticity of its vapour. However, the splitting of atomic bromine apparently proceeds with the participation of atomic oxygen and, in the case of argon (at the interaction with OH-radicals), products of water molecule splitting. The energy of the $\text{Br}-\text{C}$ bond is much greater than that of the $\text{Br}-\text{Br}$ bond. It accounts, probably, for the fact that the process of accumulation of a sufficient amount of fumaric acid proceeds more slowly than in the presence of bromine molecules. It is suggested that the oxygen molecules which are present in the cavitation bubble are mostly used for the breakage of the $\text{C}-\text{Br}$ bond; owing to this they do not influence further development of the chain reaction of the isomerization of maleic acid into fumaric acid.

It should be emphasized that we failed to initiate any isomerization reaction by means of bromo-benzene or sodium bromide instead of dibromo-ethane.

Thus, initiation of chain reactions in an ultrasonic wave field is probably due to the direct excitation of the initiators of these reactions, which penetrate into cavitation bubble. In some cases chemical transformations can bring about the formation of the intermediate reactions, the products of which can be initiators of chain chemical processes.

EVIDENCE FOR MICROFOSSILS IN THE ALAIS AND ORGUEIL
CARBONACEOUS METEORITES

By SAM L. VANLANDINGHAM

Department of Biology, University of Louisville, Kentucky

ACHEMICAL treatment of powdered samples of the Alais and Orgueil carbonaceous chondrites, using concentrated hydrofluoric acid or 6 N hydrochloric acid and/or a solution of saturated potassium chlorate with concentrated nitric acid (Schulze's solution), resulted in the isolation of a number of acid-resistant particles which morphologically resemble organized elements described by Claus and Nagy¹, Staplin², Timofejev³ and Palik⁴. Some of these particles appeared to be morphologically identical with the microstructures described by the same investigators and were found, by Nagy *et al.*⁵, to be partially mineralized. A few of the acid-resistant particles were identified as recent terrestrial contaminants; however, the majority of them appeared to be indigenous microfossils on morphological grounds. The fact that some of the microstructures in the Alais meteorite are identical with those in the Orgueil meteorite (obtained from a different museum) and that no microstructures were found in the Bruderheim meteorite (a non-carbonaceous chondrite used as a control) serves as a further indication of a possible indigenous origin of the microfossils.

Approximately 670 mg of the Alais meteorite, 470 mg of the Orgueil meteorite and 680 mg of the Bruderheim meteorite were obtained from Dr. George Claus, New York University. These samples originally came from the American Museum of Natural History, New York, from the Smithsonian Institution, Washington, and from the University of Alberta, Canada, respectively. The Alais meteorite fell in 1806 in France, and was chemically studied by Berzelius⁶ in 1834. The Orgueil meteorite fell in 1864 in France and it has been the subject of extensive investigations in recent years. The Orgueil meteorite contains hydrocarbons⁷, fatty acids⁸, porphyrins⁹, and organic material which shows optical rotation¹⁰. Free-carbon radicals of possible biogenic origin were also found evenly distributed in some meteoritic organic phases¹¹. Mineralogical investigations^{12,13} have shown that its parent body had an aqueous, low temperature, slightly alkaline and somewhat reducing environment. The interior of the meteorite did not seem to be affected by the heat generated during the fall through the Earth's atmosphere. The Bruderheim meteorite fell in Canada in 1960 and it has been used widely in recent chemical and physical investigations. It is a non-carbonaceous chondrite containing minerals of high-temperature origin only; consequently it appears to be a suitable control for the present studies.

The Alais meteorite was crushed in a glass mortar. The powder was first treated with 75 ml. of concentrated hydrofluoric acid for 24 h at room temperature and then washed and siphoned six times with distilled water, allowing 2 h for each settling between siphonings. The distance of settling was 40 cm. The purpose of the hydrofluoric acid treatment was to remove silicate minerals. The material was then treated with approximately 75 ml. of Schulze's solution in order to bleach concentrated organic remains. After approximately 24 h in the Schulze's solution, the samples were washed and siphoned six times, allowing 2 h for each settling between siphonings. A water suspension of the cleaned organic and insoluble material was mixed with 'Clearcol' resin on glass cover-slips. The cover-slips were then placed on glass slides and allowed to dry. Fragments of the Orgueil meteorite were treated only with Schulze's solution.

In another experiment, approximately 373 mg of the Alais meteorite were crushed in a glass mortar and treated with 75 ml. of concentrated hydrochloric acid for 12 h. The samples were washed and siphoned six times, allowing 2 h for each settling of 40 ml. The acid-resistant remains were then mounted in 'Hyrax' resin. The same procedure was also followed for the Bruderheim and the Orgueil meteorites.

A microscopic examination of fifteen slides revealed some terrestrial contaminants. A fungus spore and some spores or pollen grains were noted in the Alais and Orgueil meteorites. The contamination level appeared to be low; only five slides out of the fifteen microscopic preparations showed microstructures that could be identified possibly with recent organisms. In the Bruderheim meteorite no contaminants were observed.

Figs. 1-4 show photomicrographs of some of the acid-resistant particles separated from the Alais and Orgueil carbonaceous meteorites. Thirty indigenous forms were

Figs. 1-4

found. Some of them appear to be identical with microstructures described by earlier investigators¹⁻⁴. Fig. 1 shows a laminar particle, slightly folded, having a small papilla, and with a width of 27μ . This form is from the Alais meteorite, and it is considered to be identical with forms described by Claus and Nagy from the Orgueil and Ivuna meteorites¹⁴. Fig. 2 shows a flat, disk-shaped body with perforations and spines. The body has a diameter of 10.5μ . This form was found in the Alais meteorite. Fig. 3 shows a spherical body, $28-31\mu$ in diameter, exhibiting a thin-wall structure. This form was found in the Orgueil meteorite. Fig. 4 shows an oblong body which is punctate to granulose and which has a conspicuous triradiate tubular wall thickening resembling a canal-like structure. The wall is thin. This body has dimensions of $17\mu \times 20\mu$ and was found in the Alais meteorite. A detailed micropalaeontological report on these and the remaining forms will be published elsewhere¹⁵.

The work recorded here confirms earlier findings regarding the presence of microstructures in carbonaceous meteorites. These have been identified by some investigators as only biological contaminants^{16,17}. The exact origin

of the organized elements is still not known; however, it does not seem to be likely that all microstructures can be accounted for as either recent biological contaminants or mineral artefacts.

INHIBITION OF TRANSPLANTABLE AND SPONTANEOUS MURINE TUMOURS BY THE M-P VIRUS

By DR. NORMAN MOLOMUT and DR. MORTON PADNOS

Waldemar Medical Research Foundation, Inc., Woodbury, Long Island, New York

TWO years ago we reported that while studying subcellular fractions of Ehrlich ascites carcinoma (EAC), we noted that after 105,000g centrifugation the supernatant fluid was capable of transmitting EAC when injected into mice. Subsequent investigations revealed viable cells with vacuolated cytoplasm and nuclei compressed into evaginations of the cell wall present in the supernatant fluid¹.

Filtration of the final supernatant fluid on a 220-m μ 'Gradocol' membrane removed these cells and the filtrate did not transmit EAC when injected into mice. However, the filtrate, after injection, caused a mild disease grossly characterized by lassitude, ruffled fur, and swollen abdomen (ascites fluid) from which the mice recovered within 10-18 days varying with each inbred strain of mouse. The peripheral blood exhibited a marked lymphocytopenia, and our subsequent investigations determined the presence of a virus^{2,3}.

The major findings accompanying the viraemia in all strains of mice consist of a marked lowering of the peripheral blood lymphocytes, reduction in cells and size of the spleen, lymph nodes and thymus accompanied by the development of peritoneal and pleural fluids in Swiss mice. These reactions occur also in rats, and to a limited extent in young cats and dogs where the dose of virus may be too small to induce more marked symptoms. The peripheral blood lymphocytopenia is sustained on re-infection with virus given prior to development of neutralizing antibodies².

In contrast to the effect on lymphocytes and lymphoid tissues *in vivo*, the virus is not cytopathic for normal mouse cells in culture. We have quite recently observed that, after two culture passages in a primary isolate from a transplanted mouse passage lymphosarcoma, the M-P virus (designation of the new isolate) was cytopathic for the lymphosarcoma cells. The cytoplasm became vacuolated, cells swelled, nuclei appeared granular and many cells became multi-nucleated. The M-P virus appears to differentiate between normal and malignant cells of the same type, and we propose to pursue this aspect further.

The physical and chemical properties of the virus determined so far are the following: stable at -20°C in serum

for 16 months (the period of time so far tested); labile at 56°C in serum after 30 min, and in saline dilution it loses its infectivity rapidly, with retention of activity for less than one week at -20°C ; filtration on 180 m μ 'Gradocol' membranes retains the virus; the supernatant fluid after 5 h centrifugation at 105,000g in a Spinco model L is still infective for mice; the virus will not haemagglutinate bovine erythrocytes, which differentiates it from the Reo III and related viruses; it is not inactivated by RNase treatment; and is labile at pH 3.0 in glycine hydrochloride buffer.

The post-viraemic serum and organs of mice yield a haemagglutinin for sheep red blood cell (SRBC), which is not produced in cell culture. The haemagglutinin has been separated by differential filtration and absorption on SRBC from the M-P virus particle. Neutralizing antibody for the M-P virus does not react with the haemagglutinin and the haemagglutinin does not neutralize the M-P virus.

Serological tests utilizing haemagglutination inhibition, complement fixation, and infectivity neutralization methods were used to examine this agent. Serological cross-reactions were noted with antisera to the mouse leukaemia viruses of Moloney, Rauscher, and, to a lesser degree, the Friend virus. However, when these antisera were absorbed with normal mouse thymus cells, there were no cross-reactions.

No cross-reactions were noted with the following viruses: mouse hepatitis (MHV), Kilham (K), mouse pneumonitis (PVM), Reo III, and polyoma. Complement fixation tests with the antiserum to the M-P virus and LCM virus antigen indicate that there is a serological commonality between them. The control mouse sera from normal mice gave an anomalous reaction in that one of the sera was also positive for LCM virus antigen. The LCM virus is not infective by intracerebral inoculation in mice previously immunized to the M-P virus. The *in vivo* pathology induced by the LCM agent, however, in susceptible non-immune mice differs strikingly from that caused by the M-P virus. This would lead us to believe that the M-P virus and the LCM virus may both be part of a class of viruses which have some characteristics in common,

but differ markedly in size, pathological effects *in vivo* and anti-tumour action on both transplantable and spontaneous tumour in mice.

The marked lymphocytopenia induced by injection of the M-P virus directed our attention to the possible anti-leukaemic action of this virus and afterwards to its effect on other transplanted and spontaneous tumour in mice.

The transplanted tumours examined were the following: a lymphoid leukaemia induced by methylcholanthrene in BALB/C mice in 1960; Ehrlich ascites carcinoma obtained from Dr. Sugiura in 1960; a spontaneous C₃H mammary carcinoma in the second mouse passage; spontaneous lymphatic leukaemia in AKR mice.

Transplants of equal numbers of lymphoid cells in controls and mice injected with a single dose of M-P virus (500 × ID₅₀) administered 24 h after inoculation of the leukaemic cell result in a mean increase of 40 per cent in survival beyond the controls, and with the smaller transplanted dose of leukaemic cells, 55 per cent of the mice survived the leukaemia. No survivors had evidence of leukaemic involvement at 18 months.

Following the same experimental model with Ehrlich ascites carcinoma, 80 per cent of the M-P virus treated mice survive as compared to only 18 per cent controls².

Table 1 summarizes results from the second passage transplant of the spontaneous C₃H mammary carcinoma.

The experimental model varied with respect to the time of virus injection and tumour transplantation; one day prior to tumour transplant, and 12 days after tumour transplant when the graft was palpable, with appropriate tumour graft controls.

The virus-treated mice show a marked slowing of the progression of the subcutaneous transplant when the virus is administered one day before as well as 12 days after tumour graft. (Statistical probability less than 0.01 per cent, due to chance.) The tumour graft did not grow in four of the mice injected with M-P virus one day prior to tumour graft.

In an investigation (now in its tenth month) control mice have developed and died of lymphatic leukaemia, while two groups of mice treated with M-P virus (administered a single intraperitoneal injection of the MPV), one group treated at three months of age and another group treated at six months of age, reveal marked inhibition of leukaemia with the latter group showing complete suppression (Table 2).

The effect of the M-P virus in suppressing spontaneous C₃H mammary carcinoma is current, with the following data in hand; female mice from our C₃H breeding colony were weaned from their third litter, separated into a control and treated group using litter mates; one month after weaning, mice of one group were treated with a single intraperitoneal injection of the virus, and their respective litter mate controls were injected with the diluent only. The data at six months since the injection of the virus are presented in Table 3.

Table 1. M-P VIRUS INHIBITION OF TRANSPLANTED MAMMARY CARCINOMA IN C₃H MICE
(Second mouse passage from spontaneous tumour)

	No. mice	500 ID ₅₀ Virus dose injected	Average tumour size mm ² (after 1 month)	P(%)
Tumour control	100	None	308 ± 20.1	
Virus and tumour graft	95	1 day prior	202 ± 16.5	0.01
Virus and tumour graft	120	12 days after graft	175 ± 11.8	0.01

Table 2. INHIBITION BY M-P VIRUS OF SPONTANEOUS LEUKAEMIA IN AKR MICE

Group and treatment	No. of mice	Sex *	No. of mice dead with leukaemia/Total mice
(I) Control	28	F	17/28
No treatment	23	M	4/23
(II) M-P virus at 3 months	21	F	11/21
8 months	8	M	0/8
(III) M-P virus at 6 months	21	F	0/21
18 months	18	M	1/18

* No. of male mice reduced by early deaths due to injuries resulting from fighting within pens.

Table 3.

	No. of mice	Tumour incidence 3 months	6 months	No. of mice without tumours
Control	26	10	17	9
Virus treated *	26	3	10	16

* Litter mates were paired for each respective group.

The results from the experiments with transplanted and spontaneous tumours in mice, so far, encourage us to continue to examine the influence of this virus on other experimental tumour-host systems and to investigate the underlying mechanism for this antitumour action.

The most apparent and marked difference between this newly isolated virus and other reported mouse viruses lies in the pathological *sequelae* of the viraemia induced in mice. The pathological effects associated with this virus differ from those known to be associated with the viruses of mouse hepatitis, Reo III, the leukaemogenic murine viruses and the LCM virus.

The fifth to eighth day of the acute viraemia is characterized by a significant fall in total white blood cells, primarily the lymphocytes. Subsequent to this, the lymphocytes return to normal. The rise in total white blood cell count to levels greater than pre-infection is probably due to the stimulus of the infectious state itself. Virus is detectable in the circulating blood from 24 h to approximately 4 weeks after infection. After the 28th day no live virus is recoverable from either the blood or organs. The generalized lymphocytopenia accompanying infection with this virus is present in all strains of inoculated mice, but affects Swiss mice to a greater degree than any of the others.

A detailed report of the pathological *sequelae* of the M-P virus infection has been reported². There is an atrophy of the spleen to $\frac{1}{2}$ – $\frac{1}{3}$ the size of the normal organ resulting from two changes: first, a sharp reduction in the lymphocyte content of the pulp and of the follicles, and second, a curious gelatinoid degeneration of the perifollicular stroma with an increase of atypical megakaryocytes with multilobulated hyperchromatic nuclei. Essentially the same effects are seen in the lymph nodes and the thymus, and a degree of toxic hepatitis ranging from fatty degeneration to occasional central necrotic changes is also seen.

Both peritoneal and pleural fluids occur between the seventh and ninth day of the acute infectious stage (Swiss mice only). Live virus is recoverable from the exudate, circulating blood, and all internal organs of infected animals. In C₃H and C57BL/6 mice, in which the infection is usually less severe and which survive the acute viraemia, there is evidence of choriomeningitis in 5–7 per cent of the mice, but no actual cerebral changes are encountered.

The lymphocytopenia in the organs and blood is replaced by a lymphoid regeneration and hyperplasia with moderate congestion of the splenic pulp and disappearance of the acidophilic homogeneous matrix seen in the acute viraemic stage.

We have isolated and partially characterized a heretofore undescribed virus which differs from other viruses from murine sources. We have designated it the M-P virus. This virus does not induce any cytopathic changes in normal mouse cell cultures and, when inoculated into susceptible mice, induces a viraemia which is accompanied by a marked lymphocytopenia in the peripheral blood and lymphoid organs. Another intriguing property is the ability of this virus to suppress transplanted and spontaneous tumours in mice. Present experiments indicate that the M-P virus, though isolated from a murine source, is infective for rats, young cats and dogs, causing symptoms similar to those found in mice during the acute viraemia with no evidence of disease.

In considering the possibility that the M-P virus may be an agent worthy of trial for human anti-cancer therapy (especially leukaemias and lymphomata), we are aware of the fact that there are serious limitations to be borne in mind. These latter were commented on in an

editorial in the *Lancet* (February 13, 1965, p. 366): "... A serious limiting factor has been that immune response to the therapeutic agent renders it less effective for continued use. Also, the long-term infectivity and mutation possibilities of injecting live virus must be borne in mind".

We are, nevertheless, encouraged, because the M-P virus induces a mild, transient viraemia without serious disease of *sequelae* in experimental animals in doses which have inhibited experimental tumours.

Another point of interest from the laboratory point of view is that since the M-P virus affects lymphocytosis and reduces lymphoid organs (spleen, nodes, thymus) it lends itself to use as a laboratory tool for a re-evaluation and

examination of antibody formation, transplantation phenomena and tolerance, inflammation and wound healing in order to assay further the role of the lymphocyte in such phenomena.

We thank Miss Violet Satory, Mr. Gerard Shimonaski and Miss Judith Gruen for technical assistance during the course of these experiments.

IMMUNE SYSTEM IN A MONOTREME: STUDIES ON THE AUSTRALIAN ECHIDNA (*Tachyglossus aculeatus*)

By DR. E. DIENER*

Walter and Eliza Hall Institute of Medical Research, Melbourne

AND

DR. E. H. M. EALEY

Department of Zoology and Comparative Physiology, Monash University, Melbourne

THE phylogeny of the immune system has been investigated in some detail in lower vertebrates of different species by Good¹ and his co-workers and others. In the lower vertebrates, including bony fishes and Elasmobranchii, there is nothing corresponding to the peripheral lymph nodes of mammals. In the Amphibia we find for the first time in the phylogenetic series structures resembling lymph nodes, the so-called jugular bodies, the embryological development of which was described by German anatomists such as v. Braunmühl² in 1925. More recently, Kent *et al.*³ described the presence of pyroninophil cells in the jugular bodies of *Bufo marinus* after antigenic stimulation. Work on this species has been extended by Diener and Nossal⁴ with regard to the selective uptake and distribution of flagellar antigen and the antibody response.

There is general agreement that mammals probably derive from the mammal-like therapsid reptiles of the Triassic and Jurassic periods. However, anatomical investigations, such as those by Goodrich⁵ on the circulatory systems, demonstrate that mammals could not have evolved from any group closely related to modern reptiles. This would mean that the therapsid reptiles were derived separately from either labyrinthodont⁶ or microsaurs⁷ Amphibia. The evolutionary origin of the monotremes is obscure, but it has been suggested that they arose from the Docodonts along a line of evolution unrelated to the Pantotheria from which present-day marsupial and placental mammals are derived. It was of obvious interest to examine the immune system of the most readily available monotreme, the echidna or spiny ant-eater (*Tachyglossus aculeatus*), to determine whether there were any features intermediate between those of Amphibia and of eutherian mammals.

This article deals principally with the histo-anatomical aspects of the project. Preliminary results from an extensive experimental programme are mentioned only where relevant.

The work was based on a total of ten animals selected from a colony of 70 echidnas which is currently being used for physiological studies by the Department of Zoology and Comparative Physiology at Monash University, Melbourne. Seven echidnas were used for histological investigation which included examination of the distribution pattern of colloidal carbon and ¹²⁵I-labelled flagellar antigen from *Salmonella adelaide*, using the autoradiographic method described by Nossal, Ada and Austin⁸. In order not to deplete the colony, most tissue samples

were obtained by biopsy. Three other echidnas have so far been subjected to studies on serum antibody formation. Echidnas were kept at 20° C and maintained normal body-weight and growth rates on a diet of pulped egg, beef and milk mixed with earth and vitamins. For histological investigations colloidal carbon and radio-iodinated flagellar antigen were injected subcutaneously into the neck region for labelling peripheral lymph noduli which were sampled by repeated biopsies. Colloidal carbon was injected into the jugular vein and spleen biopsies were carried out. Tissues were fixed in 10 per cent formal-saline and sections stained with Unna-Pappenheim stain, toluidine blue, haematoxylin-eosin and periodic acid-Schiff stain. For the studies of humoral antibody-production sheep red cells were injected intraperitoneally; bovine serum albumin (BSA) and flagellar antigen were injected intramuscularly. Antibody titration was performed by the immobilization technique described by Nossal, Ada and Austin⁹ for anti-flagellar antibodies, by standard haemagglutination methods for sheep red cells and by BSA-precipitation methods using the technique of Farr¹⁰. However, neither haemagglutinin against sheep red cells nor BSA-precipitin was obtained. Even a secondary injection with alum-precipitated BSA could not demonstrate detectable antibody. The only antibody formation obtained in the echidna was after inoculation with 1 mg of flagellar antigen. However, the peak titres demonstrated by three echidnas treated with this antigen were remarkably low as compared with the normal antibody response of laboratory rats or mice. Treatment of the total antibody peak titre with 2-mercaptoethanol (ME) demonstrated the presence of 75 per cent ME-resistant antibody. Results of an extended experimental investigation of the antibody-forming capacity in the echidna will be presented elsewhere.

Lymphoid system of echidna. The major organs of the echidna, spleen, thymus and appendix, are found in the same anatomical situations as in the higher mammals. The spleen is of characteristic tri-radiate shape (Fig. 1). Great differences in spleen size in different individuals have been observed which may be the expression of different physiological states. The blood vessels supplying the spleen were large and numerous, suggesting a high rate of blood flow. Further evidence of this was found in the numerous thick-walled arterioles in the red pulp.

The most interesting feature was the presence of small and very numerous nodules of lymphoid tissue in most of the sites where lymph nodes would be expected in placental mammals.

* Supported by a Roche Fellowship.

They are present throughout the chest, neck and pelvic region characteristically in fatty tissue closely related to the main blood vessels. They can often be seen macroscopically to be related to a network of rather large lymphatic vessels. The mesenteric lymph nodules are very numerous and are solitary, although some are often larger than the nodules in peripheral tissues. They are interlinked in a web of lymphatic vessels. Tonsillar tissue was identified in the pharyngeal region closely associated with submandibular salivary glands (Fig. 2). Peyer's patches of the gut could not be found.

Histological findings

(1) *Lymph nodules*. The highly vascularized lymph nodules are the most interesting feature of the echidna lymphatic system, because they seem to be intermediate in histological organization between the jugular-bodies of the Amphibia and the eutherian lymph nodes. The jugular bodies of *Bufo marinus* merely contain an agglomeration of lymphatic cells throughout a reticulum; moreover, they have no cortical or medullary structure, neither follicles nor circular sinus. However, there is a

Fig. 1. Diagram of the echidna spleen showing the typical tri-radiate shape. Sections were taken out from parts indicated A, B, C and D

Fig. 2. Accumulation of lymphatic tissue in close relationship to the epithelium of the submandibular part of the pharyngeal region. The similarity with the tonsils of higher mammals is evident. (Periodic acid-Schiff stain: $\times 60$)

Fig. 3. Typical echidna lymph nodule showing a highly vascularized cortical zone of small lymphocytes. We believe the pale area of the nodule to be a germinal centre. (Haematoxylin and eosin: $\times c. 67$)

Fig. 4. Germinal centre of an echidna lymph nodule. Characteristic features of such centres are primitive cells often to be seen in mitotic activity. Note 'tingible body macrophages' indicated by arrows. (Haematoxylin and eosin: $\times c. 167$)

striking difference between the lymph nodes of the eutherians and the monotremes. (Histological preparations obtained from the other existing species of Monotreme, the platypus, *Ornithorhynchus paradoxus* (kindly provided by the Fisheries and Wildlife Department, Victoria), were similar to the ones obtained from the echidna.) Whereas in the eutherians a series of follicles is grouped within the diffuse cortex of each node, in the echidna each nodule appears to act as a single follicle. There is a peripheral cortical region of small lymphocytes enclosing a medullary zone which seems to represent a germinal centre containing primitive cells (Figs. 3, 4). After injection of colloidal carbon, the label accumulated within a well-developed circular sinus and the peripheral zone of the nodule, showing the fine web of phagocytic processes (Fig. 5), retained the carbon particles (as has been described in lymph nodes

of rats by Miller and Nossal¹¹). However, whereas in the rat lymph node the carbon retention occurs in close relationship to primary follicles, in the echidna the particles accumulate around the periphery of the entire nodule within 24 h and seem to spread undifferentially towards the centre. Later on, carbon can be seen throughout the medullary zone within periodic acid-Schiff-positive cells, sometimes seen particularly in association with the larger blood vessels which are evident in some of the nodules. Further investigation using the method of injecting ¹²⁵I-labelled flagellar antigen and subsequent autoradiography of the sections is in progress. Results so far have shown nothing comparable to the areas at the periphery of primary lymphoid follicles in the rat where antigen is selectively retained¹². Evidence of an immune response may, however, often be seen in the form of clusters of pyroninophil cells within zones of small lymphocytes.

Fig. 5. Uptake of carbon at the periphery of the lymph nodule of the echidna, 24 h after injection. The web-like structure throughout the cortical zone may be produced by cytoplasmic processes, retaining carbon particles. (Toluidine blue: $\times 416$)

Fig. 6. Lymph nodules of echidna seen within the lumen of a lymphatic vessel. (Haematoxylin and eosin: $\times 60$)

Fig. 7. Appendix of echidna showing lymphoid follicles each divided into cortical and medullary zone. Note the crypt in the centre of one of the follicles filled with polymorph nuclear cells (arrow). (Haematoxylin and eosin: $\times c. 41$)

In addition to this unique structure of the echidna lymph node it is of great interest that, in some regions at least, nodules are seen to be suspended within the lumen of a large lymphatic vessel (Fig. 6). This varies in its content; sometimes being empty, or with only a few lymphocytes, sometimes filled, perhaps as a result of trauma, with lymphocytes and red blood cells. It will be of great interest to follow the embryological and early post-hatching development of these structures. The appearance described might well arise by invagination of the lymphatic vascular wall into the lumen of the vessel. Subsequent vascularization of the invaginated wall could provide the appropriate meshwork, into which lymphatic cells could settle down to form a lymphatic nodule. Since the lymph nodule in the echidna seems to represent a single lymphoid follicle, one could think of a gradual evolutionary tendency of such follicles to fuse together to form the characteristic lymph node of eutherian mammals. That this process may even take place in the echidna is suggested by the occasional occurrence of such nodules which show more than one germinal centre. Autoradiographic studies of antigen distribution as well as embryological work will be necessary to work out the implications of the histological appearances.

(2) *Thymus*. Each half of the thymus is divided into numerous highly vascularized lobules. Each lobule has a cortical and medullary zone comparable with higher mammals. There are numerous Hassall's corpuscles in the medulla. As no significant difference in structure between the thymus of the echidna and that of Eutheria was recognized, further detail is not included in this article.

(3) *Spleen*. The echidna spleen was subjected to biopsies from five different positions indicated in Fig. 1. The relative proportion of white pulp to red pulp at these locations does not indicate significant structural differences within the organ. Erythrocytes can be seen not only within the red pulp but also dispersed in a characteristic way within the follicles of the white pulp, between the marginal zones and the germinal centres. These latter are similar to those found in the Eutheria, in that they contain primitive pyroninophil cells. Twenty-four hours after the intravenous injection of carbon, phagocytic cells containing carbon particles were scattered throughout the red pulp.

Fig. 8. High-power micrograph of the central medullary field of an appendix follicle. Note the cluster of epithelial cells among the lymphocytes and reticulum cells. (Haematoxylin and eosin: $\times c. 527$)

As in *Bufo marinus* and the *Eutheria* the white pulp was devoid of carbon.

(4) *Appendix*. In the appendix (Fig. 7), the lymphoid follicles generally resemble the nodules seen in subcutaneous tissue, but a very conspicuous feature in some is a central accumulation of epithelial cells (Fig. 8). The impression still to be confirmed by further investigations

is that each follicle may have arisen as an accumulation of lymphocytes around an epithelial crypt and that, as it developed, the structure of the crypt was gradually lost. In most, however, there are undoubted epithelial cells even though they are dispersed as single cells among a great excess of lymphocytes. The striking similarity between the appendix of the rabbit and the bursa of Fabricius in birds has been discussed by Archer, Sutherland and Good¹³. In comparison, the appendix of the echidna shows the same similarity in so far as there is a clear separation of the follicles into cortical and medullary zones. There is no reason, however, to suggest any homology between the echidna appendix and the bursa of Fabricius in birds. The anatomical situation is quite different, and palaeontological opinion is that birds were derived from the same archaic group, the Diadectomorpha, as modern reptiles and are far removed from the line of monotreme evolution.

We thank Sir Macfarlane Burnet for his advice, and Misses Carol Austin, Vera Hillel and Jenny Watson for their help.

PHOSPHORUS EXCRETION OF CATTLE FED ON HIGH-ENERGY DIETS

By W. D. C. REED and DR. R. C. ELLIOTT

Henderson Research Station, Mazoe, Rhodesia

AND

DR. J. H. TOPPS*

Department of Agriculture, University College of Rhodesia and Nyasaland, Salisbury, Rhodesia

HIGH-ENERGY diets composed mainly of cereal grains are now widely used in beef production in Britain¹. Such diets have been shown to be the type of ration utilized most efficiently by ruminants for fattening². Rhodesia is a maize-exporting country where yields are high; for example, 6,000 lb. of maize grain per acre are frequently gathered. In the past, some of this cereal has been fed to cattle in conventional diets, which consisted of grass hay, maize silage and a balanced concentrate containing maize grain. Recently, interest has been given to feeding large quantities of maize in a complete high-energy diet to growing and fattening beef cattle. In 1964, several thousand head of cattle were fattened for slaughter in this way.

An investigation of the metabolism of cattle, fed on diets principally composed of maize, showed phosphorus excretion to be distinctly abnormal, while symptoms typical of acidosis were apparent. A summary of the findings is given in this article.

A balance trial was carried out with four 1-year-old Africander steers, average live-weight 550 lb. They were given four concentrate diets based on maize meal with a protein-mineral-vitamin A supplement. A four-unit Latin square design was used. Each diet contained a different amount of roughage, namely 0, 10, 20 and 30 per cent respectively of the quantity of concentrate. The roughage was grass hay of low nutritive value. The diets

and their preparation will be described in full in another communication. Each steer received each diet for a four-week period, in the last week of which the nitrogen and mineral balance of the animal was determined. The results, which show the phosphorus balance of the steers, are given in Table 1.

These results show two striking features. The steers excreted a large amount of phosphorus in their urine whereas with conventional diets cattle excrete very little. Tillman *et al.*^{3,4} found that 1-year-old Hereford steers excreted only 2-4 per cent of their phosphorus intake in their urine. Although the diets contained liberal amounts of phosphorus (0.38-0.47 per cent phosphorus) compared with suggested requirements of 0.21-0.28 per cent phosphorus (National Research Council⁵), the young rapidly growing steers retained relatively small amounts. In contrast, 1-year-old dairy heifers given 3.3 g phosphorus per 100 lb. live-weight have been found to retain 1.0 g phosphorus per 100 lb. live-weight⁶, while young steers examined by Tillman *et al.*³ showed a phosphorus retention

Table 1. MEAN VALUES (G/24 H) FOR INTAKE, FAECAL EXCRETION, URINARY EXCRETION AND RETENTION OF PHOSPHORUS FOR FOUR STEERS GIVEN FOUR DIFFERENT DIETS

Diets	Intake	Excretion		Retention
		Faecal	Urinary	
All concentrate	15.2	6.3	7.2	1.7
Concentrate + 10% roughage	19.2	9.6	7.1	2.5
Concentrate + 20% roughage	19.6	11.9	5.0	2.7
Concentrate + 30% roughage*	18.2	11.3	3.9	3.0

* Mean values for three steers.

* Present address: Rowett Research Institute, Bucksburn, Aberdeen.

Fig. 1. Relationship between titratable acidity and phosphorus content of the urine of cattle given high-energy diets. $\log y = -0.74 + 0.0036x$

of 35 per cent of intake. High urinary excretion and low retention were most pronounced with the all-concentrated diet.

In a second trial, four mature Africander steers, average live-weight 1,450 lb. and fitted with rumen cannulae, were given four diets which were similar to those used in the balance experiment except that roughage was supplied by high-quality lucerne hay. Each steer received each diet for a 4-week period (Latin square design). During one day of the final week urine was collected and its titratable acidity, pH value and phosphorus content determined. Appreciable quantities of an amorphous white solid, which was found to be phosphate, followed the neutralization of many of the urine samples with sodium hydroxide in the determination of titratable acidity. A close relationship

($r = 0.804$, $P < 0.01$) was found between the titratable acidity and the phosphorus content of the excreted urine (Fig. 1). The linear regression obtained was $\log y = -0.74 + 0.0036x$ where y is the urinary excretion of phosphorus in g/24 h and x is the titratable acidity of the daily output of urine in ml. N NaOH.

Abnormally high amounts of acidic phosphate, $H_2PO_4^-$, are excreted in some forms of metabolic acidosis in humans. Through this loss, which is based on the reaction $HPO_4^{2-} + H^+ \rightarrow H_2PO_4^-$, the body excretes H^+ and conserves basic ions such as Na^+ and K^+ . The close relationship found between the acidity of the steers' urine and its phosphorus content indicates the presence of a similar effect in cattle fed on high-energy diets. It is relevant to note that Elam, Ham and Dyer⁷ found that the phosphorus content of urine was significantly increased when steers were given potassium acid phosphate.

The results of the two trials show that cattle given diets rich in maize excrete between 10 and 20 times the normal amounts of urinary phosphate, and that the titratable acidity of their urine is high. This is characteristic of metabolic acidosis. Previous workers^{1,8} have found that cattle fed cereal-rich diets suffer from a form of acidosis which is associated with depressed appetite and a stiff, inco-ordinated gait in the hind limbs. Attempts to alleviate this condition by the provision of basic sodium and potassium ions in the form of sodium and potassium acetates⁹ or sodium bicarbonate¹ have not been successful. The results of the work recorded here suggest that artificial increase in the phosphorus content of high-energy diets may counteract acidosis and maintain the food intake of the animal. Such practice may be needed also to supply rapidly growing young animals with sufficient phosphorus to meet metabolic requirements, since the retention of phosphorus supplied in high-energy diets appears to be relatively low.

This work was supported by the Rockefeller Foundation and we thank Dr. J. Oliver for advice.

HYPERLIPAEMIA FOLLOWING VIRAL INFECTION IN THE CHICKEN EMBRYO: A NEW SYNDROME

By DR. S. E. GROSSBERG and PROF. W. M. O'LEARY

Department of Microbiology, Cornell University Medical College, New York, and Service de Physiologie Microbienne, Institut Pasteur, Paris

DURING investigations of viral interference with Japanese encephalitis (JE) virus in the chicken embryo, it was noted that plasmas from JE virus-infected embryos were turbid. This cloudiness rapidly progressed in relation to infection so that, by the third day after allantoic inoculation of virus, plasmas appeared creamy (Fig. 1). This opalescence occurred within two days after infection whether embryos were inoculated into the allantois at 12, 13, 14 or 15 days of embryonic life. A search of the literature has not revealed any report of such a phenomenon, even by workers studying growth of JE virus in the chicken embryo¹⁻³. In such investigations, however, either strains of virus were used which were rapidly lethal for the embryo¹, or embryos were utilized at an early stage of their development^{2,3} when they were unable to resist the virulent effects of JE virus⁴.

The JE virus strain M5/596 used in these investigations produced an inapparent infection in chicken embryos 12 days or older^{4,5}. This strain of virus was isolated from mosquitoes naturally infected in Japan⁶ and had been through 9-10 passages in suckling mouse brain. Stock virus was prepared as a 10 per cent suspension of suckling mouse brain in Hanks's salt solution containing 0.1 per cent bovine albumin, penicillin, 100 units/ml., and streptomycin, 100 µg/ml., and stored in sealed glass ampoules at -60° C. Virus was diluted in Hanks's solution with 0.1 per cent bovine albumin, penicillin, and streptomycin. Diluted virus (0.1 ml. containing 10^6 or 10^7 LD₅₀) was inoculated into the allantois of White Leghorn chicken embryos previously incubated at 38° C; infected embryos were subsequently incubated at 35° C. Embryos were bled into plastic syringes wetted with either heparin or 0.2-M

Table 1. GROWTH OF JAPANESE ENCEPHALITIS (JE) VIRUS IN THE CHICKEN EMBRYO AFTER INTRA-ALLANTOIC INOCULATION*

Embryonic material	Titre of JE virus after inoculation†		
	6 h	24 h	48 h
Allantoic fluid	2.5	4.1	5.1
Plasma	1.9	3.7	4.8
Brain‡	—	2.8	5.4
Liver‡	—	2.9	5.6

* $6.3 \log_{10} LD_{50}$ in inoculum.† $\log_{10} LD_{50}/\text{ml.}$ calculated from the mortality of mice following intra-cranial inoculation (0.03 ml.) of decimal dilutions (5 mice/dilution) of pools of material taken from 4 embryos at each time interval.‡ Supernatant of a 20 per cent suspension (centrifuged at 800 *g*) made in 0.1 per cent bovine albumin in Hanks's salt solution with penicillin and streptomycin.

versene from an allantoic vein through a window cut in the shell. Blood from four to nine embryos was usually pooled at a given bleeding, and the plasmas stored at -60°C .

JE virions inoculated into the allantois, an extra-embryonic organ, multiplied rapidly, then gained access to the embryonic circulation, and subsequently grew in intra-embryonic organs, for example, brain and liver (Table 1). Afterwards interferon was found in organs in the embryo and was thought to account for survival of the embryo until the time of hatching². Infected embryos delayed their hatching an additional 1–2 days beyond the usual 21–22 days, under the temperature and humidity conditions used. Infected chicks could peck a hole in the shell and appeared to breathe and cheep normally. Only a rare chick was able to peck its way completely out of the shell; for those which could not, removal of the shell allowed them to hatch. However, all chicks were unable to stand and were considerably smaller than uninfected chicks. Although no gross deformities or organic abnormalities were evident, the chicks usually died within another 48 h.

The remarkable opalescence of the plasma of JE virus-infected embryos was reminiscent of the fat-laden serum of diabetic patients in acidosis. To prove that turbidity was due to the lipid material, a series of experiments involving gravimetric analysis, thin-layer chromatography, and gas chromatography were instituted. Before these could be performed with safety, it was necessary to free the plasmas of infectious JE virus. Since JE virus contains lipids⁷, its infectivity should be readily inactivated by treatment with diethyl ether⁸. However, after treatment of infected plasma with as much as 5 volumes of ether at 4°C for 2 h, $1.5 \log_{10} LD_{50}$ of JE virions remained of the original $5.5 \log_{10} LD_{50}$. The plasmas, therefore, also had to be heated at 60°C for 60 min to free them of detectably infectious virus. Heating was afterwards incorporated into the first step of the extraction procedure.

Extraction and gravimetry were done by a modification of the method of Entenman⁹ using ethanol-ether extraction at 60°C followed by filtration, evaporation to dryness under nitrogen, and re-extraction of the residue. The results of gravimetric analysis of a representative experiment are shown in Fig. 2 where very marked increase in

Fig. 2. Results of gravimetric analysis of total lipids in the plasmas of chicken embryos infected with Japanese encephalitis (JE) virus and in plasmas taken simultaneously from uninfected control embryos.

the amount of total plasma lipids was noted in JE virus-infected chicken embryo plasmas. A minimal increase in total plasma lipids of uninfected embryos was noted over a longer time period.

Thin-layer chromatography of total plasma lipids was performed on silica gel by standard methods¹⁰ utilizing petroleum ether/ethyl ether/acetic acid (90/10/1) or chloroform/methanol/water (65/25/4) as developing solvents. Spots were detected after development of the plates by two methods in sequence: (1) spraying with 2,6-dichloro-fluorescein for examination under ultra-violet light; (2) spraying with concentrated sulphuric acid and heating at 130°C for 30 min to char areas containing carbon. Plates were spotted with 300- μg samples dissolved in 100 μl ether. In normal plasmas there was a progressive increase of cholesterol esters with time and a decrease in triglycerides, free fatty acids, cholesterol, and phospholipids, in agreement with published data¹¹. In JE virus-infected embryos, however, there was a drop in cholesterol and cholesterol esters 3–4 days after infection, while there was an increase in triglycerides and phospholipids.

For gas chromatographic analyses, plasma lipids were hydrolysed, freed of non-saponifiable matter, and methylated with the use of boron trifluoride, as described in detail elsewhere¹². The ester mixtures were then analysed by gas chromatography using a Perkin-Elmer model 154-D fractometer fitted with a 2-metre 0.25-in. column with diethylene glycol succinate as a stationary phase. The analysis of the fatty acids recovered from a 16–18-day pool of normal embryonic plasmas showed the presence of tetradecanoic, hexadecanoic, hexadecenoic, octadecanoic, octadecenoic and octadec-dienoic acids in proportions that are in accord with published data¹¹. Analyses of fatty acid mixtures from the plasmas of JE virus-infected embryos of similar age revealed increases in the amounts of hexadecenoic and

Fig. 1. Progressive appearance of lactescence in the plasmas of chicken embryos infected with Japanese encephalitis virus in contrast with those of uninfected control embryos.

octadec-dienoic acids. No unusual fatty acids were detected.

Porterfield and Rowe¹³ have demonstrated that certain serum fractions which contain lipid, including β -lipoproteins, inhibit the haemagglutination of JE virus, among other group B arboviruses. It was of interest to determine whether the increased lipids found could be associated with plasma protein components. Standard electrophoresis¹⁴ on normal and infected plasmas was done in agar gel using 0.05 M veronal buffer at pH 8.2; proteins were stained with azocarmine, and fats with sudan black. A striking increase in β -lipoproteins and the fat associated with them was noted by day 3 in JE virus-infected plasmas.

Whether this response of the chicken embryo to JE viral infection is a specific one is of interest. Preliminary investigations indicate that influenza virus and *Escherichia coli* inoculated into the allantois produce some lipaemia not comparable to that seen with JE virus, whereas *Staphylococcus* and Rous sarcoma virus do not.

The mechanism of the remarkable hyperlipaemia following Japanese encephalitis virus infection initiated in the allantoic sac is not clear.

It is possible that this neurotropic virus destroys fat-rich neural tissue with subsequent mobilization into the circulation. Histopathological study of the major tissues of the embryo did not show any inflammatory or destructive changes in neural tissue, but a hepatitis became evident by days 3 and 4. This was characterized by marked variation in fat distribution, diminished appearance of total fat, greatly increased haematopoiesis, and a few haemorrhagic lesions. No other organ was noticeably involved at this time. This hepatitis, heretofore unreported following JE virus infection in the chicken embryo, became evident long after the lipaemia was already pronounced, but the pathology seen undoubtedly reflects earlier sub-microscopic lesions.

The chicken embryo might be said to be on a relatively high fat diet, mobilizing lipids from the yolk for oxidative catabolism or lipid anabolism. Since many of the lipids of the embryo are produced as well as withdrawn from the circulation by the liver and partly by the yolk sac membrane^{11,15}, it is very possible that dynamic imbalances between the two processes may result in hyperlipaemia. Another possibility is that embryonic cells in liver and elsewhere are only sufficiently damaged by viral infection to initiate an increase in intracellular lipid stores, as has been demonstrated in cell culture¹⁶, with subsequent release of lipids into the circulation. The most attractive hypothesis, which does not exclude the above possibilities, is that a specific host enzyme or enzyme system, necessary for lipid metabolism, is suppressed by JE viral infection. The depression of host protein synthesis and enzymatic activity, which occurs early in viral infection, is

an apparently general cellular phenomenon¹⁷. Inhibition of lipoprotein lipase might account for this phenomenon; the turbidity of plasma of infected embryos bled after intravenous administration of heparin did not clear, whereas normal embryo plasma did show lipase activity. A viral-induced lipoprotein lipase deficiency would focus the defect in endothelial cells in which JE virus has been shown to multiply¹⁸.

It is tempting to speculate that such a lipaemia plays a role in host resistance. Certain lipid-containing, and therefore lipophilic viruses, bind to cholesterol, palmitic acid or hexadecylamine with varying affinities^{19,20}. Lipid inhibitors in serum might act by preferential binding of virions and thereby limit adsorption of virus to the lipoprotein receptors for virus which are normally present in cells.

Since the precise mechanism(s) involved remains obscure, the association of hyperlipaemia, hepatitis, and JE viral infection merits further study.

We thank Miss Janet Louis and Miss Claude Guyot-Jeannin for technical assistance, Dr. Robert Skarnes for aid with the electrophoresis of plasmas and Dr. J. C. Guillon for review of the histopathological sections. One of us (S. E. G.) thanks Dr. André Lwoff for his hospitality and for stimulating discussions.

This work was supported in part by grants from the New York Health Research Council (U-1432), the American Cancer Society (IN-73C), and the U.S. Public Health Service (AI-03327-D). One of us (S. E. G.) is Markle Scholar in Medical Sciences, on leave at the Pasteur Institute 1964-65 from Cornell University, and has received an award under the U.S. Public Health Service research career award programme (AI-K3-9915).

CHROMOSOME MARKER STUDIES ON THE DEVELOPMENT OF THE HAEMOPOIETIC SYSTEM IN THE CHICK EMBRYO

By M. A. S. MOORE and Dr. J. J. T. OWEN

Physical Anthropology Laboratory, Department of Human Anatomy, University of Oxford

A NUMBER of investigations have shown that placental interchange of blood in multiple mammalian pregnancies results in blood cell chimaerism in the adult animal¹⁻⁵. In addition, there is evidence that movement of erythrocyte precursors occurs during avian embryogenesis. Thus erythrocyte mosaicism has been demonstrated in chicks derived from double-yolked eggs⁶ and from eggs parabiosed during incubation⁷. These investigations suggest not only that there is movement of blood-forming cells between embryos sharing a common circulation, but also that such cells may become established and persist

into adult life. However, a direct study of the population of embryonic haemopoietic organs by blood-borne cells has not been made.

For a number of reasons the chick embryo provides an ideal subject for such a study. First, male (ZZ) and female (ZW) avian cells can be readily distinguished from each other in good chromosome preparations as the Z chromosome is the only large mediocentric element present. Secondly, avian embryos can be parabiosed at

TOWARDS A PUBLIC UNDERSTANDING OF SCIENCE

The Architecture of Molecules

By Prof. Linus Pauling and Roger Hayward. Pp. x+117 57 full-page drawings). (San Francisco and London: W. H. Freeman and Company, 1964.) 70s.; 10 dollars.

WE are now living in an atomic age. In order to understand the world, every person needs to have some knowledge of atoms and molecules."

This is the beginning paragraph of a fascinating work of art: *The Architecture of Molecules*, by Linus Pauling and Roger Hayward. The question as to how some understanding of science, however superficial, can be brought to the man and woman in the street has exercised many organizations as well as individuals. At a practical level, of course, it is unnecessary to know anything about electric currents in order to turn a switch and bring on the light. Babies love to do it before they are one year old. But for all too many people science is still magic even when they are twenty-one. They eat their food and hope that it will be digested. They give their car petrol, oil and water and expect that it will go. They put their vote into a ballot-box and leave someone else to make all political decisions for them. Furthermore, so long as there is a doctor to write out a prescription, a garage man to look at the motor when it stalls, a strike-leader to tell them when to stop work or a horoscope to tell them when to expect a change for the better, why worry?

Well, Linus Pauling worries. He thinks, quite rightly, that young people ought to want to know why the 'lead' of a pencil comes off on to the paper, what an atom of hydrogen or uranium 'looks like', how many different kinds of atoms there are and why a scientist refers to silver as Ag, why so many different models are used to represent molecules and what holds atoms together in molecules. He goes on to discuss the valencies, sizes and shapes of molecules, from H_2 to the antiviral aureomycin, $C_{22}H_{23}O_3N_2Cl$, and the even larger myoglobin and haemoglobin. He explains in terms of the strain of bent bonds and the eclipsed orientation of the hydrogen atoms why cyclopropane is a better fuel for rocket propulsion than cyclopentane or cyclohexane. He also shows how molecular shape may be responsible for disease and abnormality in human beings. Roger Hayward's drawings are superb. Every crystallographer will want to possess this book and so gloat over them. Undoubtedly many an arts sixth-former will pick the book off the school library shelf and will learn a great deal by browsing through it. So indeed will those science students who are bound to read anything that Linus Pauling writes. (Incidentally, it is a pity that in the definition of liganey, in section 29, the word is misprinted 'lignancy'.)

It will be interesting to see whether the book will appeal most to those who are already scientists or to the man-in-the-street for whom it seems to be intended. To an experienced reader this book tells a great deal about the interests of Linus Pauling himself. It is just a little difficult, otherwise, to explain the absence of benzene and the presence of $Pt_4(CH_3)_{16}$, or of the catenane ($C_{34}H_{66}O_2 + C_{34}H_{68}$). The linking of molecular structures and of crystals with the Platonic solids, and hence with the ancient symbols for earth, air, fire, water and the ether, is historically interesting, but one feels uneasily

that it could also be misleading. Nevertheless, it is difficult to be critical for long of a book with such unusual personality about it. It is too fascinating.

KATHLEEN LONSDALE

AFRICAN STUDENTS IN BRITAIN

New Commonwealth Students in Britain

With Special Reference to Students from East Africa. (A P.E.P. Publication.) Pp. 253. (London: George Allen and Unwin, Ltd., 1965.) 35s. net.

IN October 1964 there were 64,169 overseas students in the United Kingdom, of which 42,323 came from Commonwealth countries—the East African contingent numbering approximately 4,000. The figures for 1965 are not yet available but they are likely to show an increase. Moreover, there are probably as many again in other countries in Western Europe, the United States, India and in Communist countries. The magnitude of the problem does not seem to be appreciated by the general public, although it is a source of continuing anxiety to the authorities and organizations which have to deal with the students.

Political and Economic Planning has sponsored a study by a research team into the problems of East African students in Britain, financed by a generous grant from the Ford Foundation. The report which covers the thoroughgoing investigation is a valuable contribution to our understanding of the problem. It is not possible in a short review to cover the whole report and we must confine ourselves to a few salient points.

First we may enquire why there is an influx of East African students on this scale. The most obvious reason is that despite the considerable and costly expansion of post-secondary educational establishments in East Africa, it is quite insufficient to meet the demand. The newly independent countries are in a hurry to 'Africanize' and are doing everything possible to step up the output of secondary schools. In Kenya, for example, the Government plans to provide an additional 21,000 secondary school places by 1970, and Tanzania and Uganda are doing likewise. It seems most improbable that the University of East Africa and technical training establishments will expand sufficiently rapidly to meet the greatly increased demand for places. The inevitable answer is to seek places in educational establishments overseas. That this is recognized by the local governments is demonstrated by the fact that in Kenya the Ministry of Education's vote for post-secondary scholarships has been increased by £480,000 per annum. Another reason is that a number of students consider that an overseas qualification has a prestige value greater than one gained in their own country, although some suffer disillusionment when they return home and find that their degrees or diplomas are not of the standard required by their own Governments. This is not, however, the case with most qualifications gained in the United Kingdom, the standards of which are acceptable. Even so, in order to gain a professional qualification students sometimes have to learn subjects which are useless to them. For example, students training in England as accountants have to study the British income tax laws. But such anomalies do not deter those who are often more concerned with gaining an acceptable qualification than with what they have to learn.

The chapters of the report which are of particular interest and importance are those dealing with the life in Britain of new Commonwealth students. The report makes it clear that despite what students are told they find themselves in many important respects treated as foreigners and lead a life very different to that of British students. The material conditions—finance, climate, health, food and accommodation—are very different from those to which they are accustomed at home. This emphasizes the importance of adequate preparation before they leave their own countries. Of particular importance is the choice of a suitable course of study. In the past most students who come to the United Kingdom with Government scholarships have been free, on their return home, to choose such employments as they fancy. But now the tendency is for Government scholarships to be 'bonded', which means that successful students will be required to enter a career chosen for them by the Government of their country, at least for a number of years. There are many who disapprove of this interference with the individual freedom, but the Kenya Government thinks otherwise and this adds emphasis to the great care needed to ensure that a student studies a subject for which he has aptitude.

Government-sponsored students are usually provided with sufficient funds to live without being unduly troubled with financial worries and in any case they have their High Commissioners to turn to when in difficulties. On the other hand, private students are left to their own devices. In many cases they are financed by their parents or relations, who make great sacrifices on their behalf. The cost of study abroad is often underestimated and private students frequently find themselves genuinely short of money and have to earn in their spare time, which inevitably reduces their capacity for study. Except when looking for accommodation or work, coloured students do not complain unduly of racial discrimination, although it exists more than it should in places of entertainment, restaurants and public houses. The impressions students take home of attitudes of people in the United Kingdom are bound to affect their outlook and there is much scope for improvement in the relationship of the people of the United Kingdom with the overseas students in their midst.

Finally there is a formidable list of recommendations as to what the British Government, the Overseas Governments and the educational and other institutions in the United Kingdom should do to improve matters. The list is too long to comment on here, but all who have anything to do with overseas students should read this report and study the recommendations with the view of assisting in the alleviation of the lot of these men and women who are destined to play a vital part in the future of their own countries.

TWINING

VIEWS OF NINETEENTH-CENTURY SCIENCE

Science in the Nineteenth Century

Edited and with a Preface by René Taton. (A General History of the Sciences.) Pp. xix+623+69 plates. (London: Thames and Hudson, Ltd., 1965.) 126s.

OF no period more than the nineteenth century is the lack of a synoptic treatment of the history of science more marked; for that reason alone the appearance of the volume under review, purporting to be a translation of Volume 3 of *Histoire Générale des Sciences*, aroused in my mind keen expectations of interest and profit: it must be confessed that these expectations were realized only in a very limited degree.

In the "Préface générale" to the first volume of the original edition René Taton stated that the aim of the series

was to provide "un tableau objectif et suffisamment précis de l'évolution d'ensemble de l'histoire générale des sciences et des techniques considéré comme l'un des aspects essentiels de l'histoire des civilisations". In the volume under review the reader is prepared for the survey of "one of the most essential aspects of the history of civilizations" by means of three pages on "The Spirit of the Nineteenth Century". The result may well be imagined but when we are told, *inter alia*, that "until 1815 human geniuses were few and far between . . . in the nineteenth century, however, geniuses were both numerous and identifiable" it is difficult to avoid a feeling of chill as to what lies ahead of us. These fears are unfortunately soon realized. There are, for example, in the subsequent chapters far too many 'births', 're-births', 'true births' etc.—the 'real birth' of projective geometry was with Poncelet (p. 20), but only with Chasles (p. 21) was "the projective doctrine truly born"; "geometrical optics was born in the 17th century" (what then had Ptolemy and ibn al-Haitham been doing?); "the science of electricity began at the end of the 18th century" (p. 100), but (p. 178) "by the end of the 18th century all the basic principles of electrostatics and magnetostatics were known". Some of these parturitions seem to have involved irregular intra-uterine interference; for although spectrum analysis was 'born' only in 1859 (pp. 146-7) it was "given a tremendous boost" in 1814 (p. 146). In fairness to the authors of these and many similar doubtful statements the possibility could not be ruled out that some change of emphasis had occurred in translation; so having read the whole of the English version I turned to the French original with which I had had no previous acquaintance. By chance my first comparison was in respect of the statement (p. 250) that "it follows from the preceding discussion [Carnot cycle] that the work done in any reversible process must be zero". In the French original (p. 279) there is no reference to 'work done'; the discussion has merely to do with the emergence of the concept of entropy.

The discovery of such apparently gratuitous alteration of the French original (resulting in this case in a statement that is literally false) made it necessary to compare more than a score of similar cases. The results can only be described as disconcerting. A few examples must suffice: a footnote omitted (p. 50); the discussion of what the translator calls Poincaré's "commodism" ('conventionalism'?) follows (p. 107) lines quite different from those of the French (p. 118); "courant électrique" (p. 130) becomes "electromagnetic [-motive?] force" (p. 118) "théorie électromagnétique . . . de la lumière" (p. 162) becomes "discovery of the electromagnetic effect" (p. 145); a paragraph is omitted (p. 157); "à ce sujet" (p. 194) becomes "his explanation" (p. 171); the exposition of Raoult's work (p. 288) is largely rewritten (p. 258); "conception métaphysique" (p. 303) becomes "metaphysical fog" (p. 272). On p. 477 the translator, perhaps with the British market in mind, intercalates more than a page on the Huxley-Wilberforce incident to which there is no specific reference in the original. Finally, disconcerted by what seemed to me an oversimplified and inadequate supported version (allegedly by Taton, from whom one was surprised to find such a statement) of the organization of science in Great Britain, I was shocked to discover the complete omission of a scrupulously worded warning by Taton that, because of the paucity of detailed studies (Dr. Cardwell's excellent work finds no mention in his bibliography), the account presented must be accepted with great caution. Nor was this all: Taton's account had been so re-phrased as to convey the impression that the Cavendish Laboratory had been set up by the British Government instead of, in Taton's words, "grâce à des fonds privés"—incidentally of a member of the despised Establishment (*sic* referring to 1872!).

The translation of a work of this kind calls for very wide knowledge; and in providing a smooth and readable

ersion A. J. Pomerans has risen to the challenge. But hope enough has been said (and much more could be) to justify the complaint that the publication of this book 'as a translation', without any indication in the bibliographical note on the verso of the title-page that it is far from being so, constitutes a grave injustice to the original authors and does a signal disservice to British scholarship.

In the space at my disposal I can do no more than present a few personal impressions—with the caveat that they are based on the book which I have been called on to review and not on what the authors may or may not have written.

Apart from the brief but useful sketches of "Science and Society in Russia" (A. P. Yushkevitch and the late V. P. Zubov), "United States" (I. B. Cohen), "The Muslim World 1450–1900" (B. Ben Yahia), all the contributors are French; yet there is a marked freedom from national bias: M. Jacques Levy's evaluation of the Le-Verrier-Adams case is a model of human and technical insight. From the section (77 pages) on mathematics (Taton, Itard and Darrois), highly technical as at many points it inevitably becomes, a reader with no more than the very meagre mathematical understanding that I myself possess should be able to gain a valuable idea of the progressive 'arithmetization' and increased abstraction whereby mathematics acquired more and more relevance to natural science. M. Bauer's remarkable survey of the whole of "Electricity and Magnetism" from Galvani to Lorentz is nicely balanced between the 'continental' view and Faraday-Maxwell innovation (see p. 216). The "Rebirth" [original *Essor*] of Chemistry" by Daumas and Jacques is about as good as could be expected in 34 pages (out of 153 for "Physical Science", excluding mechanics and astronomy!), but Wilhelm Ostwald, for example, gets only a passing nod. The splitting of science into the traditional 'subjects' has the serious consequence that the long struggle to perfect the idea of 'atomicity' as such falls between 'chemistry' and 'molecular kinetics'; hence (together with the complete omission of Herapath and J. J. Waterston) the misleading statement on p. 265. The part played by "Geological Sciences" is attractively sketched by MM. Orcel and Furon. But the appalling problem of presenting a 'unified' but not over-simplified view of nineteenth-century biology has not yet been solved; I was struck by the fact that only where judicious citations of the original works were provided (as by M. Piveteau in "Comparative Vertebrate Anatomy" and "Vertebrate Palaeontology") did the history really come alive. The presentation of a mass of 'systematic' information (though well done by Mlle. Tétray) seems out of place in a work of this kind; similar remarks apply to almost the whole chapter on "Medical Sciences" (M. Astruc).

Among many old favourites there are some excellent lesser-known illustrations. The "Bibliography" should be very useful, as should the indexes of names and subjects; in the latter, however, the only possible reference to "Alternation of Generations in Plants" (pp. 467–8) is "Alteration", and this turns out to refer only to animals. One regrets the omission of 'life-spans' in the name index, and throughout the book there is a paucity of cross-references and, in many chapters, of dates.

RACES, GOALS AND ALL THAT

Heredity and the Nature of Man

By Dr. Theodosius Dobzhansky. Pp. x+179. (London: George Allen and Unwin, Ltd., 1965.) 25s. net.

DOBZHANSKY's new book is based on a series of "Holiday Science Lectures" given under the auspices of the American Association for the Advancement of

Science, in the spring of 1963 and 1964. The purpose of these Lectures is "to broaden the scientific horizons of the audience, and to communicate to them some of the excitement and inspiration of the scientific endeavour". What one may expect, therefore, and what one gets in full measure from Dobzhansky, is popular science writing at its best. It would be improper to look for any radically new additions to the general theory of evolution, on which Dobzhansky is one of the world's foremost authorities. Nor do we find any quite novel suggestions as to how our understanding of evolutionary processes should be applied to human affairs.

The first half of *Heredity and the Nature of Man* is mainly devoted to giving a summary sketch of basic facts. Even in this Dobzhansky reveals his judicious middle position, by devoting much more space than is usual in elementary texts to the contributions which the environment, as well as the genes, make to the character of the final adult organism. He shows in simple and convincing terms that it is nonsense to attribute overwhelming importance either to heredity as some eugenicists have done, or to suppose that any human individual is infinitely malleable by suitable training, as some anthropologists have tended to argue. It is, however, in the second part of the book, when he applies the basic principles of genetics to such questions as human equality and race, that he best demonstrates his skill at steering between Scylla and Charybdis. The danger of a middle position is of wriggling out of a difficult situation by an exercise in 'double-think'. Occasionally one may get the impression that something of the kind is going to happen. For example, in discussing the relevance of the undoubted genetic differences between individuals to the concept of human equality, Dobzhansky writes, "The partisans of equality . . . simply failed to understand that to be equal is not the same thing as to be alike". However, he goes on to state explicitly what this implies, and demonstrates that it is by no means merely a semantic quibble: equality is an ethical and sociological, not a biological, ideal, and its practical effect is to give to each man an equal dignity and an equal opportunity to develop just because he is a unique (that is, 'unequal') individual. Dobzhansky is not afraid to point out that equality of opportunity does not mean mere uniformity. The opportunity must be judged in relation to the potentialities to which it is offered; the schooling provided for the average of the population may represent a most unfair deprivation for individuals who happen to be particularly talented in mathematics, music or various other special fields.

He is equally sensible about the other major areas in which genetics has impinged on public affairs. For example, he deals very justly with the evolutionary dangers of the extra mutations produced by ionizing radiation, which seemed so urgent when we first had to consider the effects of bomb fall-out. Discussing race, he castigates both "the racists who believe that culture is a matter of race . . . of the genes of the carriers of that culture", and the belief that, "as far as cultures and their changes are concerned, all people are genetically so completely identical that their genes may just as well be left out of consideration". The truth is somewhere in between the two and, although we do not know exactly where, it must be much nearer the second than the first. He makes the essential point that "human genetically secured educability enables most individuals of all races to be trained for most occupations". In his final chapter he is, I think, a trifle too conservative in his attitude to some of the more unconventional genetical procedures, such as the use of artificial insemination with selected gametes.

In all the great human questions that Dobzhansky discusses, genetics is only one aspect of a complex problem which also involves the human sciences, and politics and morals in addition. For example, the most important question about race at present seems to be the speed at

which the change of cultural level can be brought about by social means. Cultures certainly have a property analogous to inertia, and the problem now is not whether there is any genetical reason why you could not train an adequate number of Congolese or Indonesians to be efficient modern administrators and managers—Dobzhansky argues convincingly enough that there is no such reason—but how to do it as fast as possible and with the minimum damage to other important values such as 'equality'. Problems of this kind fall outside the scope of the book, but if the reader realizes that he must not expect to find the final answers to all problems, he can be assured that Dobzhansky provides, in a form suitable for the general reader, including scientists from other fields, a clear, concise and judicious summing-up of the main conclusions that genetics has come to about human nature and human affairs.

C. H. WADDINGTON

FROM FORSTER TO FISHER

Education and the Labour Movement 1870–1920

By Brian Simon. (Studies in the History of Education.) Pp. 387+29 plates. (London: Lawrence and Wishart, 1965.) 50s. net.

THE light industry of scholarship often obscures the fact that history is really concealed prophecy. Mandates to explain how things came about imply opinions as to where they are going. Those who accept them cannot avoid seeing their subjects in terms of the future. At the present our educational future is very much in the mind. Are we, the post-Robbinsians, structuring the 'open conspiracy' of which H. G. Wells was such a fervent advocate? Will our future Samurai of scientists, engineers and teachers demand an equally radical approach to those who sell the labour of their hands? What are we doing to counter the growth of Orwellian 'proles'? Will they transform themselves out of existence as we have known them?

Such questions need a long cool look at the role of the Labour movement in our recent history, and everyone will agree that in Mr. Brian Simon it has found a historian of outstanding merit. All his previous work has contributed to this role. His *A Student's View of the University* (1943) is now a minor classic; his *Intelligence Testing and the Comprehensive School* (1943) a pioneer work; his *Common Secondary School* (1955) offered a classic paradigm of the comprehensive school; and his *Psychology in the Soviet Union* (1957) brought together expositors from fields too little known in Britain.

Education and the Labour Movement 1870–1920 is virtually a continuation of an earlier, and by now standard, work: *Studies in the History of Education 1780–1870* (1960). It charts the development of Labour's aspirations up to the end of the First World War. As with its predecessor, it splices telling illustrations into a crisp and sparkling text, spikes narrative with pointed documentary evidence, and laces controversial issues by mature judgments and shrewd comments. If there are omissions (and Francis Galton is one) these have been in the interests of a flowing story. His story embraces the rise of Socialism, the pressures of the 'protean' working-class groups, the institutional and legislative embodiments of their aspirations, assessments of their abreaction to existing institutions, and their influence on the development of the welfare services.

The 'New Feudalism' of the settlement movement, the 'consolidation of caste' in the public and grammar schools, the pejorative adjective 'elementary', the militancy of the churches and the spice of sect all glow balefully in these pages as Mr. Simon threads his way, like an experienced galactic traveller, through the misty ways of educational debate and intrigue. He plots a fascinating course, since his characters were working for the future. His story is,

if anything, an apt illustration of the truth that you can only understand a movement by pointing to what it was before it becomes that which it will presently cease to be. For though writing about the period from Forster to Fisher, he is giving us the necessary canvas of the period from Fisher to Crosland, a canvas which I sincerely hope he will find time to paint to complete what will undoubtedly be a formidable trilogy of volumes.

For Socialism, as William Morris observed, could only be won by educating people into wanting it and then organizing them into claiming it. But educating people into wanting it was not as easy as organizing them into claiming it. Consider only Sidney Webb, surely the most mobile competitor in (and later the improver of) the nineteenth-century examination stakes. "Discreetly following behind the imperialist banner" (to quote Mr. Simon), Webb helped anaesthetize the school boards themselves a nursery of working-class politicians. Webb was more a portent than an educational apparatchik. Many another was to come up in twentieth-century Britain through the ladder he so eagerly rung. Those who profited by education did not always remember the steps by which they had ascended.

H. G. Wells described the Education Act of 1870—the year in which Mr. Simon begins his history—as one "to educate the lower class for employment on lower class lines". But he also wrote in the year after Mr. Simon's story ends: "Science will endure and rule, but Labour with a capital 'L', as the name of a class of human beings organized for distinctive class ends, will pass away". Labour's efforts tend to their own extinction. As a former editor of *Nature* (to whom Wells wrote those words) replied, "If labour will but listen and act it may become the most potent moving force of the future, but if it concentrates attention entirely upon scrambling with capital for the pennies in Tom Tiddler's ground of industry, the wise men around will give to it merely a tolerant smile".

Mr. Simon's story of how the Labour movement responded to this appeal will be eagerly awaited if it is written with the same verve and charm as this one.

W. H. G. ARMYTAGE

KEPLER'S DREAM

Kepler's Dream

By J. Lear. With the full text and notes of *Somnium, sive Astronomia Lunaris* Joannis Kepleri, translated by P. F. Kirkwood. Pp. 182. (Berkeley and Los Angeles: University of California Press; London: Cambridge University Press, 1965.) 40s.

FIRST written in 1609, but published only in 1634 four years after his death, Kepler's *Somnium, sive Astronomia Lunaris* introduces his ideas on the geography and physics of the Moon with a half allegorical, half science-fiction tale involving a "Daemon" who describes his travels there; the device of a didactic trip to the Moon had previously been used by the Greek writer Lucian in the second century A.D. Based on Copernican principles and therefore theologically 'hot', the Latin manuscript of 1609 was designed for limited circulation among scientists who were expected to divine the meaning hidden beneath the allegory. Unfortunately, the effect was precisely the opposite of that intended, since it was wholly ignored by scientists but fell into the hands of malicious persons in the small Württemberg town of Leonberg, who very probably seized on a fanciful reference to the hero's mother's ability to conjure the "Daemon" and twisted it in order to accuse Kepler's own mother of witchcraft. A copy of the manuscript was also believed by Kepler to have found its way to England, and its possible influence on contemporary English literature has been explored by Prof. Marjorie Nicolson, but the evidence

that this happened is not conclusive. During the decade between his mother's eventual acquittal in 1621 and his own death, Kepler took time off from the preparation of his major works of this period to embellish the original text of the *Dream* with several times its own length of footnotes giving those literary and scientific explanations of the narrative that had been proved necessary by bitter experience.

Most of the scientific part of the *Dream* is a sober exploration of the astronomical phenomena observable from the Moon as a result of its orbital motion with one face permanently turned towards the Earth; this part would be entirely acceptable to-day apart from the fact that the Sun's distance is underestimated by a factor of six. However, Kepler also believed that the Moon had air, water and inhabitants who sheltered from the extremes of heat and cold in caves; the arguments on these subjects in the notes, and the precautions suggested for the journey to the Moon, throw an interesting sidelight on his impressive physical knowledge.

John Lear has performed a useful service in commissioning this excellent translation and in providing a fascinating introduction in which the importance of this forgotten work is pointed out and the baleful effects of the misinterpretation of the 1609 manuscript are reconstructed for the first time on the basis of the notes in the 1634 edition. My only criticism refers to one passage where Lear seems to have confused nautical miles with statute miles and consequently credits Kepler with a less accurate estimate of the Moon's distance than he actually possessed.

BERNARD PAGEL

MOON AND PLANETS

Lunar and Planetary Surface Conditions

By N. A. Weil. (Advances in Space Science and Technology, Supplement 2.) Pp. ix+222. (New York and London: Academic Press, 1965.) 80s.

THE majority of books devoted to so wide a subject as planetary physics are composed of specialist sections that an editor attempts (rarely with high success) to weld together. Perhaps, in such cases, the initial conditions are not sufficiently firmly stipulated to ensure uniformity of style; or the authors who are selected are not able to present a full cross-section of the field defined in the title, and hence there are glaring omissions from the presentation.

Possibly these drawbacks may be overcome if one man alone prepares the whole account. Yet, with the rapidly multiplying amount of lunar and planetary literature, can one author have a sufficiently wide knowledge of the many and varied subjects involved to be in a position to present an authoritative review of the astronomy, physics, geology, and biological aspects of the planets? In *Lunar and Planetary Surface Conditions* Dr. Weil has bravely attempted this task.

An introduction serves to review the present hypotheses on the origin of the Solar System and describes the methods of acquiring planetary data. Approximately one-third of the book pertains to lunar studies—principally the surface aspects of the Moon—and the remainder deals with the conditions on the terrestrial and Jovian planets.

There has been drastic selection of the 293 references from the fund of available literature, but they have been well chosen and, pleasingly, there has been emphasis on recent work. Omissions from Dr. Weil's arguments are extensive and frequently yield to a biased account. For example: "Three theories exist regarding the origin of the maria" (p. 44). According to the author, these are Gold's, Urey's and Baldwin's. In fact, there are others—that of von Bülow, for example—that receive no mention although they may be even more important. Again, both the optical measurements of the way different parts of the

Moon scatter light and the polarization measurements on flat and inclined parts of the Moon point to a remarkably uniform structure of the Moon's surface layer, yet Dr. Weil writes, "... for exposed lunar surfaces, a totally different terrain is expected to be encountered on the maria as compared to the highlands" (p. 92). The inclusion of some arguments at the expense of others may have been imposed by the necessity for brevity, but is this justified in a review costing 80s.? Because of faults of this nature the book—which has a good index—will be of limited use to research workers. But the present work may be described as an excellent skeleton on which to build a future, somewhat enlarged, edition. If a second edition were to include a wider and deeper understanding of many of the vitally interesting points touched on by Dr. Weil, it could undoubtedly become of great use as a reference work.

G. FIELDER

A SURVEY OF THE EARTH

A Planet Called Earth

By Prof. George Gamow. Pp. x+257. (London: Macmillan and Co., Ltd., 1965.) 35s. net.

MORE than twenty years ago the book *Biography of the Earth*, by George Gamow, achieved wide popularity as an introduction to earth science written for the layman. There have been many scientific advances since then, and the author has wisely re-written the book completely instead of trying to patch up the original. The general plan remains the same; like its predecessor, *A Planet Called Earth* is informative and well written, so that it will no doubt be equally successful.

The first three chapters are mainly astronomical, and concern the formation of the Earth and other bodies of the Solar System, together with brief descriptions of the Moon and planets. This section is needed, because the Earth is, after all, only one of nine planets, and the comparisons between it and our neighbour worlds are well worth making. It is interesting to note that the author tends to favour the theory that the Earth and Moon were once one body, and that the Moon broke away in the fashion supposed by George Darwin in his book written during the nineteenth century. Most authorities have the gravest doubts about this process, but Gamow is careful to emphasize that there is no general agreement about the birth of the Moon.

The rest of the text deals with the Earth itself; its internal constitution, the shaping of the world map, weather and climate, and the atmosphere. The nature and origin of life, and the Earth's future, are also dealt with in a readable, concise manner.

The material has been selected with skill, and has been presented in a most attractive form, so that the reader with no previous scientific knowledge will be able to follow it throughout; mathematics are to all intents and purposes excluded. The line drawings are good, and the photographs are satisfactorily reproduced. It must be added, unfortunately, that there are a few slips, mainly in the astronomical section; for example, there are more than the stated 40,000,000,000 stars in our Galaxy (p. 22), and it is surely misleading to refer to a solar flare as "a tongue of flame" (p. 181). On page 43 the author falls into the trap, common among non-selenographers, of rejecting the volcanic theory of lunar craters simply because these main features of the Moon differ in form from Earth volcanoes such as Vesuvius.

These are, however, minor points, and in no way detract from the excellence of the book. Within its scope, it is probably the best of its kind, and it will further enhance Prof. Gamow's reputation as one of the most skilful of modern scientific writers. It deserves a wide circulation, and will certainly run to many editions before it, too, needs complete re-writing.

PATRICK MOORE

LILIENTHAL'S ATOMIC YEARS

The Journals of David E. Lilienthal

Vol. 1: The TVA Years, 1939-1945, including a Selection of Journal Entries from the 1917-1938 Period. Pp. xxxi + 734. Vol. 2: The Atomic Energy Years, 1945-1950. Pp. x + 666. (New York and London: Harper and Row, Publishers, 1964.) 150s.

THESE volumes contain the diary records of a great American, usually written by him in shorthand and later transcribed by a secretary. They were started during his freshman years as a youth of seventeen, and continued throughout the period when he was a director of the Tennessee Valley Authority (T.V.A.), and chairman of the United States Atomic Energy Commission. The entries were "jotted down at irregular intervals and in all manner of places at odd moments", in aeroplanes, even on holiday in Martha's Vineyard or Florida—holidays often interrupted by telephone calls from the T.V.A. or the Atomic Energy Commission.

Volume 2 opens with the appointment of Lilienthal, together with three others, to advise Dean Acheson, the Assistant Secretary of State, on action to be taken on the Truman-Attlee-King declaration of November 15, 1945, proposing the establishment of a U.N. Atomic Energy Commission to develop a proposal for international control of atomic energy.

After less than two months the 'Acheson-Lilienthal' Report proposed the establishment of an international atomic energy authority to have the exclusive control of all 'dangerous' aspects of atomic energy. The 'dangerous' areas included the operation of uranium mines, reactors, diffusion plants. The United States proposals were at once hindered by the appointment of Bernard Baruch, at the age of seventy-five—referred to in subsequent notes as "the old man"—as the member of the United States of the United Nations Atomic Energy Commission. Baruch immediately appointed his own panel of advisers, who had somewhat different views from the Lilienthal group. One of their early proposals was that the United Nations "should organise a world survey of raw materials and to send 50 Two-Man-Teams all over the world. In this way they would find out what was going on in Russia." The Baruch team appeared also to be obsessed with the idea of vetos and punishments for infringements. However, Acheson and Lilienthal were able to resist most of the proposals of the Baruch group.

Gromyko countered for the U.S.S.R. by proposing an international convention against atomic weapons, but without any inspection for clandestine activities. The East-West positions were incompatible and with our knowledge of the climate in the U.S.S.R. in the post-war years the United States plan was doomed to failure.

In September, 1945, after considerable congressional opposition, Lilienthal was appointed chairman of the Atomic Energy Commission established by the McMahon Act. An extremely difficult organization had been laid down in the Act—five Commissioners were jointly responsible for policy, but the chairman had no formal executive responsibility, this being devolved on a general manager. This form of organization led later to some difficulties, especially with Admiral Lewis Strauss, who was often in a minority of one. He sometimes refused to accept the majority decisions and intrigued outside the Commission to have their decisions overthrown.

The first major disagreement came over a trivial matter—the export of radioactive isotopes to Norway. This was agreed to by the Commission by a majority of 4 to 1, but Strauss attempted to take the decision to the State Department and to secure its reversal. This incident showed the dangers of a lack of scientific understanding in men in high places.

The journals give an account of co-operation with the United Kingdom. War-time collaboration had, of course,

been very close, and through it Britain had obtained a complete knowledge of the theory and construction of atomic bombs and nuclear reactors of outputs of up to a few megawatts. Britain was not allowed information about plutonium production plants; but this was of no great consequence. Churchill and Roosevelt at Hyde Park in 1944 agreed that the atomic bomb would continue to be constructed only in the United States, and that the United States would not use the bomb without the consent of the United Kingdom. The United States agreed to co-operate fully with the United Kingdom and Canada in post-war military and commercial atomic energy development unless and until terminated by Government agreement. The information about this agreement was not passed down by the President, and was not even known to Mr. Stimson, Secretary of State for War, six months later. The United States Senators were informed for the first time about this agreement by Lilienthal in December, 1946, and this came as a considerable surprise. Technical co-operation had, in fact, largely ceased after the passage of the McMahon Act. However, the agreement on the sharing of uranium supplies, operated by the Combined Development Authority, continued, and gave rise to some difficulties in the Senate, since in the years up to 1950 the United States was short of uranium supplies for its rapidly expanding programme of fissile material production, including the building of more Hanford reactors for the production of plutonium and the construction of more diffusion plants.

Eisenhower, who at this time was Chief of Staff, is quoted as saying that "denial of Atomic Energy information to the British was harsh and unfair". Lilienthal was in favour of increasing co-operation and was supported by the State Department, and in January 1948 a *modus vivendi* was arrived at in which co-operation was agreed in a number of areas. Some of these areas, such as health and safety, and nuclear physics, were unclassified areas. One of the important areas was co-operation on "Reactors in which the power was not wasted". This allowed discussions on power-producing reactors to proceed, but excluded discussion on production reactors such as Hanford. At this time ideas on power production were, in fact, rather nebulous, though E. O. Lawrence is quoted as saying that power could be produced by the Hanford reactors within a year—at that time the cooling water emerged at rather low temperatures.

The President, Mr. Truman, spoke to Lilienthal "of what wonderful things we could do with our stocks of nuclear material. I've been dreaming of T.V.A.'s in the Euphrates Valley to restore that country to fertility and beauty of ancient times, and also a T.V.A. in the Yangtze Valley and in the Danube. These things can be done and don't let anyone tell you different".

Lewis Strauss again opposed co-operation: "He feels Britain is far to the left and might give away the secrets to the communists".

Towards the end of 1949 the *modus vivendi* was extended in time and the United States was given a greater share of ore as a *quid pro quo*. Britain refused, however, to transfer bomb production to the United States and continued to ask for a complete interchange of all technical information.

In point of fact Britain was very little handicapped by lack of information from the United States on the nuclear reactors or on any civil application. Britain could, however, have been saved some expense and time by interchange of military information.

The journal records the conflict between the Atomic Energy Commission and the Department of Defence on the issue of civil versus military custody of atomic weapons. A crucial meeting was held between the President, the Heads of Service Departments, and the Commission. The Secretary of Air, Mr. Symington, remarked: "Our fellows at Sandia think they ought to have the bomb. They think they might get them when they need them and they might not work". The President replied: "You have to

understand that this is not a military weapon. It is used to wipe out women and children and unarmed people and not for military purposes. So we have got to treat them differently from rifles and cannons and ordinary things like that". The President decided that the Atomic Energy Commission should retain custody.

In October 1959, after the explosion of the first Russian atomic bomb, the issue of the hydrogen bomb known as the "Super" was debated within the Atomic Energy Commission's General Advisory Committee, chaired then by Robert Oppenheimer. The General Advisory Committee was very much divided. Conant was flatly against it: "We have built our Frankenstein"; Oppenheimer was against; Rabi was for; Lilienthal against. We know from later evidence that there were doubts about its technical feasibility and that later work transformed the situation.

A special committee of the National Security Council, Schleson, Johnson (Secretary of Defence) and Lilienthal, reported to the President, who ruled in favour of developing the "Super" (January, 1950).

Lilienthal was almost continuously attacked and vilified by some members of the Joint Congressional Atomic Energy Committee. Senator Hickenlooper charged the Commission in 1949 with gross mismanagement, and a Committee investigation proceeded under the glare of television lamps for several weeks. Complete trivialities were discussed, such as the loss of a few milligrammes of enriched UO_2 at the Argon Laboratory, later found in a dustbin. A great fuss was made about a *March of Time* film containing pictures already released in 1945. The Committee insisted on a full F.B.I. clearance for A.E.C. Fellows appointed for basic research in Universities. At one meeting of the Committee, "7 Senators and 8 Congressmen were busy reading a security file on a Miss B. employed at Los Alamos—about her drinking habits and where she slept—the great issues of co-operation with the U.K. had to wait".

President Truman told Lilienthal, "Don't let this tempest in a teapot get your goat, Dave. You let it get under your hide and you'll get like Forrester [committed suicide May 22, 1949]; no need worry about it".

The diaries reveal Lilienthal as a very humane man, much troubled by the implications of the nuclear bomb for the world; striving always to ensure that their implications were discussed at the highest policy-level. Truman is revealed as a very shrewd person; a person of vision, firm in decision and well able to handle military departments and their demands.

J. D. COCKROFT

QUASARS

Quasi-Stellar Sources and Gravitational Collapse

(Including the Proceedings of the First Texas Symposium on Relativistic Astrophysics.) Edited by Prof. Ivor Robinson, Prof. Alfred Schild and Prof. E. L. Schucking. Pp. xvii + 475. (Chicago and London: The University of Chicago Press, 1965.) 10 dollars; 72s.

QUASI-STELLAR *Sources and Gravitational Collapse*, appearing 18 months after the first Texas Symposium on Relativistic Astrophysics to which it refers, is already a historical document. It has been overtaken by the second 1964 Conference, by preparation for the third and by a series of discoveries of such moment and at such a pace that the normal media of publication have been more than usually inadequate.

In 1960 the combined work of the radio and optical astronomers led to the identification of the radio source known as 3C 295 (the number in the Cambridge Catalogue) with a cluster of galaxies in Bootes. This was the most remote object known—about 4,500 million light years distant with a red shift of 0.47. There seemed no immediate hope that a significant increase in the penetration of the telescopes might help to resolve the arguments

about the type of cosmology applicable to the real universe. Yet the search for more distant objects which was then in progress is really the starting point of this book.

Palmer and his collaborators at Jodrell Bank had found that two radio sources in the Cambridge Catalogue 3C 48 and 286 had angular diameters less than 2 sec of arc—much smaller than that of the Bootes source and hence by implication more distant. Accurate positional measurements of these sources at Cambridge and at the California Institute of Technology enabled Sandage to identify 3C 48 late in 1960 as a sixteenth magnitude blue star. For more than a year it seemed that 3C 48 and the other objects similarly identified were luminous blue stars in the Milky Way. Then early in 1963 came the famous announcement that the 'stars' were, in fact, objects with exceedingly large red shifts.

So much has happened since then that it is important to remember that at this Texas Symposium in December of that year only half a dozen of these quasi-stellar radio sources, or quasars, had been discovered and the red shifts of only four obtained. This included the red shift of 0.545 for 3C 147, making it the most distant object then known. Thus the observational and theoretical papers in this volume are based on these data, which are a small part of the information available to-day on the quasi-stellar sources. (At least 40 are now known with 18 red shifts.)

The theoretical papers are predominantly concerned with the properties of massive objects and with the possibility that the great energy of the radio galaxies and quasars (more than 10^{60} ergs in some cases) may be released through the processes of gravitational collapse. Of course, the energy difficulties existed for the radio galaxies long before the discovery of the quasars, but the latter added the additional problem of the energy needed to sustain the great luminosity of these objects. The papers offer no real solution, neither is any known to-day, although a repetition of this discussion would be likely to be far more critical of the gravitational collapse theory and speculate on possibilities of highly efficient nuclear burning or total annihilation as sources of the energy.

The observational papers include, of course, those concerned with the quasars and give the detailed arguments that the red shift is a cosmological effect and not a gravitational shift. There are, too, the valuable papers on the identification of the radio sources as a whole and their nature which have stood the test of time better than the papers on the quasi-sources.

Nearly all the papers in this volume are now reprints of existing or subsequent publications mainly from the *Astrophysical Journal* or *Nature*. The fortuitous timing of the conference does, perhaps, justify to some extent this collection as a unique mark of yet another revolution in astronomy and astrophysics which has already led to the discovery of objects with red shifts four times greater than those discussed here. The collection also enables one to express overall admiration for the outstanding observational and theoretical work of the authors, which has created a situation of unparalleled interest and potential in astronomy, astrophysics and cosmology.

BERNARD LOVELL

HURWITZ—COURANT

Funktionentheorie

Von A. Hurwitz und R. Courant. Mit einem Anhang von H. Rohrl. Vierte vermehrte und verbesserte Auflage. (Die Grundlehren der Mathematischen Wissenschaften in Einzeldarstellungen, Band 3.) Pp. xiv + 706. (Berlin: Springer-Verlag, 1964.) 49 D.M.

THE first edition (1922) of *Funktionentheorie* contained three parts. Parts 1 and 2 were based on lectures of Hurwitz. Part 1 (130 pages) expounded the

Weierstrass approach to function-theory through power series. Part 2 (110 pages) gave a fairly full account of elliptic functions, including modular functions and transformation theory. Part 3 (150 pages), due to Courant, supplemented the Hurwitz development by chapters in the geometric spirit originated by Riemann.

Even in the first edition Part 3 was largely independent of Parts 1 and 2, and in the second edition (1925) Courant expanded Part 3 into a self-contained presentation. In the third and fourth editions this tail has outgrown the dog, and I shall suggest later that two well-proportioned creatures could with advantage replace the one which has grown in an uncontrolled way.

Part 3 now fills nearly 300 pages and is an account, mainly of interest to the specialist, of the development of topological function-theory. There are other important branches of function-theory (for example, integral and meromorphic functions) for which one must look elsewhere.

The preparation of this new fourth edition is due to Prof. H. Rohrl, of Minnesota. He has revised and brought up to date the text of the third edition and has added an appendix of 150 pages (in two chapters). The additions expound the theory in the more abstract setting in which the work of the past two decades has placed it. Chapter 1 of the appendix deals with some problems of conformal representation, in particular new knowledge about prime-ends (introduced by Carathéodory in 1913) and quasi-conformal mappings. The 1-1 conformal representation of Riemann surfaces leads to a discussion of the Fuchsian groups involved. Chapter 2 of the appendix contains a clear account of selected recent investigations of compact and non-compact Riemann surfaces.

I suggest that the book, which has become unwieldy and costly, should, in future editions, become two. Parts 1 and 2 would form an excellent presentation of Weierstrass's theory for the undergraduate. Actually he would be unlikely to need so much of the detail of elliptic functions and a radical surgeon could excise some sections of Part 2. Only exceptional undergraduates would find time to read Part 3, and the others should not have to buy a large book for the sake of a small part of it. Any research worker interested in Part 3 will know what is in Parts 1 and 2 and would not refer to them except perhaps as a model of style.

J. C. BURKILL

AN ADVANCED THEORY OF VIBRATIONS

Vibrations

By Prof. D. K. Magnus. Pp. xi+299. (London: Blackie and Son, Ltd., 1965.) 65s.

VIBRATIONS certainly differs from other books about the same subject, inasmuch as it classifies the vibrations according to the mechanism from which they originate. This is reflected in an identical mathematical treatment and similar final solution. According to this classification the subject-matter is sub-divided into the following groups: (i) natural vibrations; (ii) self-excited vibrations; (iii) parametrically excited vibrations; (iv) forced vibrations; (v) coupled vibrations. This classification enables the author to deal with a variety of problems both in the mechanical and the electro-technological field in a relatively small and inexpensive book, and it seems astonishing that the subject-matter covered should form the syllabus of only one term (about four months) in a German university or technical university.

Throughout the book the emphasis is on as thorough and general a treatment as possible. For example, the section on "Damped Vibrations" covers viscous, Coulomb and square-law or turbulence friction and also non-linear

vibrations. Later in the book the response of linear systems to non-periodic inputs is dealt with, making use of Duhamel's integral. Statistically distributed excitations are also considered.

Wherever possible, exact mathematical methods are used. Extensive use is made of the phase-portrait (velocity-displacement diagram), thus, as in other ways providing a link with control systems analysis. However powerful and frequently indispensable approximation methods, such as the method of small oscillations, the harmonic balance (known as the describing function method in control systems analysis), the Ritz, the Rayleigh and the Van der Pol method of slowly varying amplitudes are not ignored.

Most of the book is devoted to single-degree-of-freedom problems and the most important methods are demonstrated on them. The treatment of systems with several degrees of freedom then offers no major difficulties.

Systems of an infinite number of degrees of freedom involving partial differential equations are only touched on in the few final pages (except the taut string which was considered at the beginning of the book), but at this stage the intelligent reader should already have grasped the most important aspects of vibrations, enabling him to embark on further problems with relative ease.

Vibrations includes carefully selected exercises for each chapter and their solutions, this making it a suitable text book for use in English-speaking universities. The translation is competent, although the translator adheres to places too closely to German wording and phrasing. It would have been helpful if, when quoting books or reference, English equivalents or existing English translations of German standard works were used, and in the case of books which had been translated from English into German, if the original titles (instead of back-translated one) were given. To sum up, it can be said that *Vibrations* is a valuable complement to existing treatises on vibrations and it can be highly recommended to all who want to penetrate more deeply into the field of vibrations.

K. R. WEISS

VIBRATION PROBLEMS IN ENGINEERING

Vibration

By Prof. R. E. D. Bishop. (Based on Six Lectures delivered at the Royal Institution, London, December 1962.) Pp. 120+20 plates. (London: Cambridge University Press, 1965.) 30s. net; 5.50 dollars.

VIBRATION is a lightheartedly written, completely non-mathematical book which arose from Christmas Lectures given at the Royal Institution to a mainly young audience. The primary purpose of the book is to explain what is involved in the profession of an engineer, and vibration was chosen as a particularly suitable field to do this. An introduction of this kind into the wide and complex field of vibrations could only be successful if supported by a number of experiments and demonstrations; these in fact accompanied the lectures, which must have been extremely interesting (and certainly sometimes amusing). The spirit of the lectures is reflected in the book, although experiments have to be described, aided by numerous plates and figures. Prof. Bishop covers many important aspects of vibrations such as: the effect of vibrations on the human body; the resistance of metals to vibration (fatigue, Wohler diagram); free vibrations; modes of vibrations (for example, demonstrated on the air-liner 'VC 10'); imposed vibrations including random vibrations; self-excited vibrations; shocks and waves.

The problems chosen as examples underline the importance of vibrations in engineering with their sometimes

pectacular effects as, for example, the resonance built up by soldiers marching in step across bridges, this having led to several disasters; whirling of shafts; the collapse of the Tacoma Bridge; fatigue failure in crankshafts and of engine compressor blades; rocking of railway trains and the wind-excited oscillations of electric transmission lines (causing short-circuiting), or of steel chimney stacks causing their collapse).

Returning to the basic purpose of the book—to explain what is involved in engineering—I should like to quote the following passage with which I heartily agree: “The idea . . . that progress is made by pure scientists having ideas, and engineers making them work, is ludicrously superficial. A successful flutter analyst has to make important decisions as a physicist, as a mathematician and as an engineer. . . . Rapid progress in any branch of engineering—not just flutter analysis—becomes possible when those who are engaged on research can cross the ill-defined frontier between pure and applied science without realizing what they have done so”.

The book will be particularly useful to the young reader looking for a comfortable way to make himself familiar with the broad aspects of vibration, or to get an idea of what is involved in engineering. He may soon, if his raining or profession lies in this field, feel the need to study a more comprehensive theoretical book (one of which has been written by the same author). Also the more advanced reader may find Prof. Bishop's elementary book pleasant reading and this may perhaps prevent him from “not seeing the wood for the trees”.

K. R. WEISS

EXPERIMENTAL PLASMA PHYSICS

Plasma Diagnostics with Microwaves

By Dr. M. A. Heald and C. B. Wharton. (Wiley Series in Plasma Physics.) Pp. xvii+452. (New York and London: John Wiley and Sons, Inc., 1965.) 102s.

THE interaction of electromagnetic waves with a plasma constitutes a very useful method of measuring three important parameters of a plasma—the electron density, the electron temperature and the magnetic field inside the plasma. The purpose of *Plasma Diagnostics with Microwaves* is to give a summary of the basic theory of this interaction, together with a description of the experimental techniques and apparatus involved. Most of the material presented has appeared in research reports written by the authors, who have been very active in the application of microwave diagnostics. However, the presentation here is in a manner and of sufficient detail to provide an excellent introduction to an experimentalist new in the field.

As implied by the title, the authors limit themselves to electromagnetic waves in the microwave region, though the theory and the basis of the experimental techniques presented are applicable to infra-red and optical wavelengths. Probing of a plasma at these wave-lengths has come into extensive use recently since the advent of masers and lasers. The plasmas under consideration are those characterized by high temperature, that is, those of high degree of ionization and low collision frequencies, and of dimensions greater than the electromagnetic wave-length. However, the diagnostics described are applicable to other plasmas.

The first six chapters are concerned with the probing of a plasma with radiation generated externally. In Chapter 1, an account of the theory of electromagnetic wave propagation through a cold plasma is given. In the next two chapters the treatment is extended to warm plasmas, and has a detailed discussion of collision processes in a plasma. Chapter 4 is concerned both with bounded plasmas and spatial non-uniformity. The choice of antenna systems for particular applications is also con-

sidered. In Chapter 5 plasmas confined in wave-guides are treated. Included is a discussion of wave-guide propagation in a plasma of both space-charge and electromagnetic waves. An extensive discussion of experimental techniques in general use is given in Chapter 6. The next two chapters are concerned with radiation in the microwave region emitted by the plasma. Both a theoretical description of the various processes by which this radiation is emitted and the details of the experiments concerned with this radiation are discussed. This is followed by a description of the experimental apparatus and the special circuits used in microwave diagnostic experiments. The final chapter is different in content and approach from the rest of the book. It consists of a list of some other plasma diagnostics with the ranges of their applicability. However, the discussion is limited to those diagnostic techniques which provide information similar to that obtained by microwaves. There are two appendixes—review of electromagnetic wave propagation and tensor and matrix algebra.

The book is very readable. The presentation is lucid and coherent. The reference list is very comprehensive and is designed to provide a means of following up those topics which of necessity could not be discussed fully. It is a very useful addition to the growing list of books available to the experimental plasma physicist.

A. E. DANGOR

ASPECTS OF RHEOLOGY

Proceedings of the Fourth International Congress on Rheology

Brown University, Providence, Rhode Island, August 26–30, 1963. Edited by E. H. Lee and Alfred L. Copley. Part 1: Pp. x+373. 120s. Part 2: Pp. xii+714. 226s. Part 3: Pp. xiii+637. 196s. Part 4: Symposium on Biorheology. Pp. xi+634. 189s. (New York and London: Interscience Publishers, a Division of John Wiley and Sons, Inc., 1965.)

ABOUT ten years ago, a fellow-rheologist commented to me: “You know, there are two kinds of rheologist, the ‘P Q’ rheologists and the ‘i j’ variety”. Until recently, the former, mainly concerned with direct relations between experimentally applied pressures and induced rates of flow, formed a large majority. From the *Proceedings of the Fourth Congress on Rheology*, one concludes that the main interest now lies in tensor theory, except perhaps in the comparatively new and popular field of biorheology, which has scarcely reached this stage. One reason for this development is that in earlier times most rheologists were trained as chemists. The new generation is composed, as is proper, of young physicists with a prime interest in applied mathematics.

The *Proceedings of the Fourth Congress* are so extensive that it was necessary to publish them to four volumes, but the arrangement is not altogether a happy one. At first sight it sounds sensible: Part 1, invited papers and general lectures; Part 2, papers from members of the (American) Society of Rheology; Part 3, other contributed papers; Part 4, a biorheological symposium. But, in fact, biological subjects are to be found in Parts 1 and 3 and other subjects are fairly evenly scattered throughout the first three volumes. These three are edited by Prof. E. H. Lee, and the fourth, independently, by Prof. A. L. Copley.

It is difficult, in a short review, to do justice to nearly 200 papers ranging in subject-matter from aluminium as an unstable solid to the properties of the skin of the hippopotamus. Suffice it to say that, throughout, the standard is very high. Perhaps the most outstanding contribution is that of Prof. C. Truesdell, who was awarded the Bingham Medal for the year. His “Rational Mechanics

of Deformation and Flow" is clearly of fundamental importance but is very stiff reading.

In all volumes except the first, the papers are grouped according to subject-matter. For some reason, Prof. Truesdell's lecture appears in Part 2 and is followed by sections on continuum mechanics, testing techniques, stress and strain distribution analysis, birefringence, metals, technology, polymers, polymer fluids, glasses, dispersions. Part 3 has sections on continuum theory, testing techniques, stress and strain distribution analysis, metals, technology, polymers, polymer fluids, polymer solids, glasses, dispersions.

The biorheological symposium (Part 4) (which is dedicated to Prof. Robin Fåhræus) is sub-divided as follows: general lectures, laminar flow, cytoplasmic streaming, haemolysis and sap movements, pulsatile flow, blood flow in branching and tapered tubes, measurements and observations, haemorheology of red cell suspensions, medical biorheology, *in vivo* haemorheology, tissue materials, blood clotting and low shear haemorheology.

It is inevitable, but a pity, that the price of this massive work will limit its circulation almost exclusively to libraries: the *Proceedings* of previous congresses have been much more condensed; but such is the present-day trend.

This is certainly a work the usefulness of which will long outlive the period before the fifth congress in Japan in 1968. As a classic, it is also good that the production, printing and style are excellent throughout.

G. W. SCOTT BLAIR

MAGNETOHYDRODYNAMIC POWER GENERATION

Magnetohydrodynamic Electrical Power Generation (Proceedings of an International Symposium held in Paris, July 1964.) Vol. 1: Papers Communications, Sessions 1 and 2, Pp. 469; Vol. 2, Sessions 3, 4 and 5, Pp. 470-1048; Vol. 3, Sessions 6, 7 and 8, Pp. 1049-1721; Vol. 4: Technical Discussion, Pp. 1722-2042. Edited by J. A. Satkowski and H. B. Smets. (Paris: Organization for Economic Co-operation and Development, 1965.) 220s.

IN 1935 the Hungarian applied scientists, Karlowitz and Halasz, patented the idea of generating electricity from the combustion of fossil fuels by means of a cycle involving the compression of the combustion air followed by the highest possible pre-heat in a heat-exchanger, followed in turn by combustion to raise the temperature as high as possible. The high-temperature combustion products were then to be expanded adiabatically to a pressure approximately atmospheric and passed at supersonic velocity through a magnetic field. Provided the gases had sufficient electrical conductivity after the adiabatic expansion, the system would thus generate d.c. as originally proposed, by the Faraday effect owing to the presence of the strong magnetic field, and the energy for this current used in an external circuit would come from the destruction of the greater part of the directed kinetic energy of the fast-moving gases. Karlowitz worked on this with a large American organization until the work was closed down by the Second World War, but the basic difficulty was the insufficient electrical conductivity of the gases. I published essentially the same idea independently in my inaugural lecture in Sheffield in 1954, and gradually during the 11 years since then pilot plant experiments both on the small and large scale have been designed and presented in a number of countries, including the United States, France, Britain, Germany, Hungary, Poland and the U.S.S.R. Similarly, engineering conferences on the subject of electricity generation from fossil and fissile fuels have been held during the past 10 years, several in Britain (the first at Sheffield in 1959), in the United States and in the U.S.S.R.

The most ambitious international symposium on magnetohydrodynamic (MHD) electrical power generation was organized by the European Nuclear Energy Agency and the French Institut National des Sciences et Techniques Nucléaires in 1964. It was attended by 400 people from 25 countries, and 114 papers were presented divided into eight technical sessions. The *Proceedings* have now been published in the form of four thick paper-back volumes with more than 2,000 pages. The titles of the eight sessions were as follows: Session 1 "Physical Properties of the MHD Working Fluid (Combustion Gas)". Session 2, "Physical Properties of the MHD Working Fluid (Closed-cycle Fluid): (a) Elementary Processes and Plasma Diagnostics; (b) Non-equilibrium Aspects". Session 3, "Study of Magnetohydrodynamic Flows and Power Conversion Processes (Continuous Gas Flows): (a) Fluid Dynamic Aspects; (b) Conversion Processes". Session 4, "Liquid Metal and Unconventional MHD Conversion and AC Power Generation: (a) Striated Flows and Explosive; (b) AC Power Generation; (c) Liquid Metal MHD Converters". Session 5, "Production of Magnetic Fields". Session 6, "Problems of Materials". Session 7, "Open-cycle Converters: (a) Experimental Aspects; (b) Prospects". Session 8, "Closed-cycle Converters: (a) Experimental Aspects, (b) Prospects".

The classical method of electricity generation from heat involves passing the heat through a boiler tube to generate high-pressure steam, the steam then expanding and pushing against turbine blades and producing rotation which is mechanically coupled to a rotating generator in which copper windings are pushed through a moderately strong magnetic field. Compared with this, the open-cycle magnetohydrodynamic system has the obvious advantage that the temperature and use of the heat are not limited either by the need to pass the heat through a pressure-tight wall or by the need to have the hot working fluid pushing against metal blades. The fundamental disadvantage of the MHD system is the fact that the metallic copper conductor is replaced in it by the working fluid and that it is extremely difficult to obtain the necessary conductivity in the gas, which has to be of the order of 100 mhos/m. As a result of the work done in the past decade, reported in this symposium, it is now clear that for the open-cycle MHD, where the working fluid contains the triatomic molecules of combustion products, it is not possible to have non-equilibrium ionization, so that the necessary conductivity can only be obtained by having gases at a temperature of the order of 2,500° K and with a seeding of a low-ionization potential material (potassium is the only economic element and even that would have to be recovered with better than 99 per cent efficiency, although fine dusts with low-work functions are also being considered). This temperature and seeding must exist under the conditions of the gases when they pass through the magnetic field; whether one uses an impulse or reaction expansion cycle, the proportion of the enthalpy of the gases which can be converted ideally to electricity depends on the total temperature drop from upstream of the nozzle to the end of the magnetic field, so that to have a large temperature drop is desirable from the point of view of output. It is also necessary even with this conductivity to have a very high magnetic field since the power generation per unit volume of the magnetic field depends on $\sigma v^2 H^2$. Schemes in the 'fifties usually involved either iron-cored magnets with a maximum field strength of 10,000 gauss, or alternatively higher fields with water-cooled copper coils and no cores. A whole session was devoted to magnetic fields in this conference and work is now directed towards achieving 100,000 gauss over large volumes usually with super-conducting coils. For these very high fields iron is not much use and the papers deal both with the optimum design of the coil, methods of cooling to have a super-conductor near a very hot MHD channel and other design features. These very high gas temperatures also involve very severe materials

problems. The British work has mainly been concentrated on water-cooled walls and electrodes with a small amount of insulation, while the French work mainly uses hot walls. The cold-wall system gives large electrode potential drop of the order of 100 V. There is a very big-scale effect and it might well be possible on the scale of 1,000 MW to have water-cooled walls while smaller systems, for example of 200 MW, might require hot walls with considerable continuous erosion.

Although the conference was organized largely under the auspices of nuclear energy, and much of the work in all countries of the world is going on in nuclear agencies, yet there is considerably more pilot-plant work being carried out on open-cycle systems aimed at combustion-heated fossil fuel usage than on the closed-cycle systems which are being considered for nuclear heat. The closed-cycle systems have the advantage that one can choose the thermodynamic working fluid to have the optimum properties, for example, helium. In this case it is possible to work at appreciably lower temperatures and have on-equilibrium ionization to give the required gas conductivity, and although seeding is still needed it is now possible to use caesium. For the open cycle one can clearly classify all the work being done into three categories; the least exciting is that in which one expects a very small Mach number, for example 0.8, for the gases for the magnetic field, and with only about 10 per cent of the energy of the fuel converted into d.c. by the MHD system while the remainder is converted into electricity by means of a conventional boiler using the heat of the exit gases from the MHD duct. It is probable that this system can be made to work, although it may well be that the small increase in efficiency of electricity generation from the fossil fuels obtained in this way (with a substantial increase in capital cost) will be overtaken by improvements in economy of conventional steam generation from fossil fuels. The second category of open-cycle MHD development from combustion is that which aims at more than 50 per cent direct generation efficiency in the MHD generator either by using a very high efficiency re-heater capable of transferring heat from waste gases at about 1 atm. pressure and $2,500^{\circ}\text{K}$ to air at some 10 atm. and rising in temperature to nearly $2,300^{\circ}\text{K}$. These systems would have to be combined with either a gas turbine or a steam turbine cycle for the lower temperatures at least to produce the compression power for the air. Thirdly, we have the more sophisticated cycles, to which a whole session was devoted. These included, in particular, the separation of the thermodynamic working fluid into striations, an idea which was first put forward in Britain and is now being actively worked on in France, the use of detonation waves to give a high-temperature, electrically conducting shock and the very interesting liquid metal converters in which the hot-combustion gases are used to impart a high velocity to a highly conducting liquid metal. It is my opinion that within the next five years there will be a break-through in one or other of these more sophisticated cycles which will change the whole situation.

M. W. THRING

ADVANCES IN FLUID DYNAMICS

Research Frontiers in Fluid Dynamics

edited by Dr. Raymond J. Seeger and Dr. G. Temple. Interscience Monographs and Texts in Physics and Astronomy, Vol. 15. Pp. ix+738. (New York and London: Interscience Publishers, a Division of John Wiley and Sons, 1965.) 230s.

RESEARCH Frontiers in Fluid Dynamics is a collection of some twenty articles on various aspects of modern fluid dynamics, each written by an acknowledged expert in his field. It is directed at the graduate student

and "intended to give him a panoramic view of some of the exciting research vistas" in the subject. The title is, in fact, slightly misleading. By no means all the research frontiers in fluid mechanics are covered and, of those omitted, some are very important and fashionable; for example, there is scarcely any mention of turbulence, instability of flow, supersonic flow, merged layers in hypersonic flow and the magneto-sphere. On the other hand, a number of very interesting fields of research are described, not all of which would be obvious to the young worker but all well worth his attention as possible areas in which useful work might be done.

It is not possible to discuss all the contributions and so I shall pick out a few which are of particular interest to me, asking the reader to bear in mind that it is a personal choice with which others might disagree. The longest chapter, by Prof. J. V. Wehausen, is on free surface flows and describes in reasonable detail the advances that have been made in this rapidly expanding field during the past few years. He covers exact mathematical theories, cavitating flow, ship waves, stratified and rotating fluids and approximate theories. Not least in importance is the list of about 600 papers in the bibliography giving the interested reader an excellent start in a subject which can be strongly recommended to graduate students. Dr. ter Haar has written an interesting article on the dynamics of liquid helium, a field in which fluid dynamicists led by C. C. Lin have begun to make notable contributions in recent years. It does not seem that the possibilities of the two-component model for helium II have yet been exhausted and it may well prove a basis for explaining its unique and fascinating dynamic properties.

Dr. Guderley gives a comprehensive account of hodograph methods in two-dimensional transonic flow, including the question of the existence of potential flows past profiles at high subsonic speeds. By way of contrast, in methods of describing research frontiers, Dr. Freeman describes one particular question in hypersonic flow—the nature of the asymptotic flow past bluff bodies—which involves a fascinating matching problem in mathematical analysis and which is still largely unsolved. One aspect of this question not discussed by the author is the possible appearance of secondary shocks.

For the more mathematically inclined student, there is a clear exposition of singular perturbation procedures, that is, Lighthill's strained co-ordinates and matched asymptotic expansions. The necessity for such sophisticated methods occurs too frequently in fluid mechanics for any theoretical worker not to have it in his armoury, and the account presented here is a good introduction. Further, the large computer is making an increasing impact in the subject and promises to be of decisive importance in the future. The article on numerical analysis by Dr. Polachek is therefore timely, for, whatever branch of fluid mechanics the student elects to work in, he will find the ideas in this chapter of assistance. There is, however, one omission, for Dorodnicyn's method of integral relations, which has had a number of successes in blunt-body aerodynamics and in boundary-layer theory, is not mentioned.

The remaining articles are: engineering aspects (W. R. Hawthorne); molecular theory of fluids (H. S. Green); viscoelastic fluids (R. S. Eivlin); anomalous viscosity (M. Reiner); second-order effects (M. Reiner); shock-wave phenomena (D. C. Pack); magneto-fluid dynamics (C. K. Chu and H. Grad); application of the Boltzmann equation of low-density flows (G. N. Patterson); high-temperature phenomena (J. D. Teare); high-density phenomena (J. S. Dahler); meteorology (J. G. Sutton); astrophysical phenomena (L. H. Aller) and fluid-dynamical problems associated with interplanetary space (E. N. Parker). Generally the contributors show a high standard of authority in their articles and infuse the reader with a feeling of the excitement, dynamism and the wide sweeping character of fluid mechanics. It should certainly be

put into the hands of postgraduate students to fire their enthusiasm for the field, but regrettably, it is doubtful whether there are any who can afford to pay the price asked.

K. STEWARTSON

PALAEONTOLOGICAL TECHNIQUES

Handbook of Paleontological Techniques

Edited by Bernhard Kummel and David Raup. Pp. xiii + 852. (San Francisco and London: W. H. Freeman and Co., 1965.) 130s.

PALAEONTOLOGICAL techniques, in the broadest sense, include searching for fossils, their collection, preparation, examination and eventual publication. Examination includes physical activities such as measurement, drawing and photography, and matters such as statistics and taxonomy. Publication involves writing and illustration. There is also storage and cataloguing. Palaeontologists generally work out methods suited to the fossils they are investigating by a combination of common sense and trial and error, although the larger museums and university departments have built up a repertory of techniques. There seems to have been an increasing number of new methods in recent years, taking advantage of new apparatus and materials, but most of the basic techniques and a number of specialized ones have been known a long time. Many papers describe individual techniques, but there has been no complete guide since the modest book by Camp and Hanna (*Methods in Paleontology*, University of California Press, 1937), which gave useful accounts of many techniques, with emphasis on vertebrates and micropalaeontology. *Handbook of Paleontological Techniques* is a new attempt to cover a field nearly as wide as that defined at the head of this paragraph.

The book consists of five parts: (1) procedures and techniques applicable to major fossil groups; (2) descriptions of specific techniques; (3) techniques in palynology (the study of pollen); (4) bibliography on palaeontological techniques; (5) list of bibliographies of stratigraphy and palaeontology. Each part consists of a number of short articles. Part 1 includes 21 essays covering most of the major fossil groups, although the ammonoids are a conspicuous omission. The essays range from chatty personal reminiscences to systematic notes on collecting and preparation. For the reader seeking practical information this is possibly the least useful part of the book, although several papers, notably that on ostracods, describe techniques in detail.

Part 2 is divided into sections on collecting, mechanical and chemical preparation, radiation techniques, casting and illustration. Most of the 13 articles in the section on collecting are either elementary (with remarks such as "Fossils are most commonly found in sediments or sedimentary rocks") or very specialized. The section on mechanical preparation has two omissions. Mechanical chisels have long been used at some laboratories, but it has been difficult to get satisfactory apparatus. An account of available machines, or constructional details, would have been useful, but only the Burgess vibro-tool is mentioned. Many makes of ultrasonic cleaning gear are now available and the palaeontologist needs guidance as to the merits of different frequencies, wide or narrow frequency ranges and different powers for cleaning fossils, but this is not given. The section on chemical methods is short (two papers) and deals only with acid treatment.

The section on radiation techniques is a good introduction for the worker contemplating the use of X-rays, ultra-violet or infra-red light, or electron microscopy in the examination of his fossils. The section on casting and moulding also gives a good account of the chief materials and methods. A fuller account of materials used for impregnating friable fossils would have been worth while.

Four of the seven articles on illustration are concerned with photography. There is also an account of ways of whitening fossils for photography, but some of the material in it is repeated in other articles throughout the book. This kind of duplication unfortunately affects a number of topics, for example micropalaeontology. The article on preparation of plates for publication is less useful than the notes for authors issued by the Palaeontological Association.

Part 3 seems to cover the specialized subject of palynology thoroughly. It occupies, however, no less than one third of the book, an unduly large proportion. There would have been a case for devoting other parts of the book to major branches of the subject. Micropalaeontology occupies about 130 pages scattered through the book. Would it not have been better to bring this material together? As it is, the information in the book is assembled partly under techniques and partly under fossil groups, which results in duplication.

Statistics might legitimately have been included. There is a useful article on sampling, but the only other paper on statistics is in the palynology section and has mathematical nomenclature beyond most palaeontologists. Similarly, zoological nomenclature concerns every palaeontologist, and an exposition of the main points of the latest rules of nomenclature would have been handy.

The difficulties of co-ordinating the work of 80 contributors are obvious. One wonders whether so many were really necessary, and whether a smaller number might not have resulted in a more compact, equally useful, book at a lower price.

D. T. DONOVAN

SOME ASPECTS OF BORON

Boron, Metallo-Boron Compounds and Boranes

Edited by Roy M. Adams. Pp. xxiii + 765. (New York and London: Interscience Publishers, a Division of John Wiley and Sons, 1964.) 207s.

THE present upsurge of interest in the chemistry of boron—until 10 or 15 years ago a very neglected element—has created a genuine need for the recently amassed knowledge to be made readily available to the enquirer and for the demands of teachers and research workers in particular to be supplied. Fortunately the compilers of such volumes have not been idle, and several unrelated books about boron have appeared in recent years, not one of which, however, provides us with a comprehensive account of the chemistry of the element as a whole and in true perspective. For this we must wait, and, indeed, there are so many new and unexpected fundamental facts about the element still being discovered that it is doubtful whether such a volume (or volume) would be well timed to appear at the present moment. We must therefore be all the more grateful for the appearance of books that deal well with certain aspects of boron chemistry, of which *Boron, Metallo-Boron Compounds and Boranes* is an excellent example.

This book is in fact a collection of eight reviews by several experts, under the general editorship of the principal contributor, Roy M. Adams. In spite of a certain unevenness—the first two reviews are relatively slight—the impact of the book as a whole is considerable, the result of careful scholarship. The scope of the book is perhaps best conveyed by its chapter headings, which are: "History and Technology of the Borax Industry", by W. A. Gale (27 pp., 141 references); "Heterogeneous Equilibria in Aqueous Systems of Inorganic Borates" by W. A. Gale (24 pp., 31 references); "Inorganic Boron Oxygen Chemistry", by N. P. Nies and G. W. Campbell (179 pp., 980 references); "Elemental Boron", by A. J. Newkirk (67 pp., 374 references); "Refractory Binary Borides", by B. Post (71 pp., 160 references); "The Hydro-

oron Ions (Ionic Boron Hydrides)", by R. M. Adams and J. R. Siedle (134 pp., 624 references); "The Boranes or Boron Hydrides", by R. M. Adams (186 pp., 804 references); "Toxicology of Boron Compounds", by G. J. Nevinskas (45 pp., 182 references).

The book is all the more welcome because, of these topics, only two—elemental boron and the boron hydrides—can be said to have been anything like adequately covered by earlier reviews, and even these are now superseded by the present contributions, which are as comprehensive as one could wish. That so much ground was relatively untrodden is a far more important factor than any criticism one might wish to raise against the book on the grounds of heterogeneity. This latter characteristic may even be considered a virtue if it can be regarded as the outcome of sensitivity of the editor to former gaps in the fields surveyed. One result has certainly been the avoidance of overlap everywhere, except to a very minor extent between Chapters 2 and 3. Perhaps the most serious aspect of the heterogeneity is the consideration that, whereas the book is obviously mainly intended for the pure chemist, the latter may justly complain that the first and final chapters have little significance for him. This is partly mitigated by the fact that, taken together, they constitute less than 10 per cent of the book. Certainly these reviews needed to be written—especially the final one, since information concerning the physiological action of boron compounds is not otherwise conveniently accessible—but the wisdom of including them in the present book is questionable.

Deserving of special mention are the chapter on boron–oxygen chemistry and the chapters on hydroboron ions and boranes. That on boranes is sufficiently up to date to include reference to the recent isolations of B_6H_{12} , B_8H_{12} and $B_{10}H_{12}$, respectively. The weakest chapter is Chapter 1, which is too brief and generalized and markedly below the high standard of the others.

To conclude, the appearance of this book is welcome and timely. It will be frequently consulted by inorganic chemists and is a 'must' for all serious boron chemists and those who are concerned with the teaching of advanced boron chemistry. The style is good and very readable throughout. Moreover, the book is supplied with good formula and subject indexes. It is strongly recommended.

L. H. LONG

PROGRESS IN PETROLEUM CHEMISTRY AND REFINERY

Advances in Petroleum Chemistry and Refining, Vol. 10. Edited by John J. McKetta, jun. Pp. xvi + 571. New York and London: Interscience Publishers, a Division of John Wiley and Sons, 1965.) 210s.

In my review of Volume 9 in the series *Advances in Petroleum Chemistry and Refining*, I wrote: "This series of volumes does, within obvious limitations, at least provide a useful means of leisure-study in the specialized subjects so far treated; to this extent it undoubtedly fills a gap in contemporary technical literature of scientific progress of petroleum technology which future volumes may well gradually narrow" (*Nature*, 207, 0; 1965). That this gap will not now be bridged is made evident in the preface to Volume 10, where it is stated by the editor, John J. McKetta, jun., that this is the final volume of the series. The initial intent was an annual publication spread over the course of several years, during which "... the series of *Advances* will have reached upon all parts of the far-flung industry, and the totality of volumes will assume the character of a reference work". Unfortunately, the co-editor, Dr. Kenneth A. Kobe, died in November 1958, not long after the series was initiated; this was followed by the death in April 1964 of a prominent member of the advisory board, Dr. Cecil L.

Brown; in these circumstances one can understand that even attaining the goal of ten volumes must have seemed an almost hopeless task, as the present editor remarks. So far, the volumes in the series have covered 96 chapters, nearly 5,600 pages, and have required the collaboration of 162 authors. It may be wondered whether another reason was instrumental in the decision to terminate the series at this juncture, namely restriction of sales, at least internationally, due to the relatively high cost of each volume, to which Volume 10 is no exception, and to which I have previously directed attention.

However, from a technical point of view, the quality and particularly the range of subjects discussed in this most recent issue are well up to the standards set by previous volumes in the series. There is a modern exposition on "The Composition of Petroleum" by R. H. Hunt and M. J. O'Neal, jun. This is followed by a chapter on "Production and Distribution of Liquid Hydrogen", by C. R. Baker and L. C. Matsch. G. P. Hinds, jun., contributes an interesting paper on "Hydrogen Conservation in Petroleum Refining". "Hydrocarbon Gasification Processes" is the joint work of G. J. Van den Berg, W. R. Dammers, and L. W. ter Haar. Dewaxing of lubricating oils has long proceeded on conventional lines but the more recent reactions to the problem are admirably summarized by the chapter on "Modern Dewaxing Technology" by S. Marple, jun., and L. J. Landry. "In the near future petroleum may replace coal tar as the primary source of naphthalene . . ." is the theme of a dissertation on "Naphthalene from Petroleum", by H. D. Ballard, jun. On the more purely academic consideration of contemporary petrochemical processes, there is the chapter on "Nonconventional Polymerization of Vinyl Monomers", by N. G. Gaylord, D. E. Hoffenberg, and H. F. Mark. Rather tangential, but none the less a welcome addition to the *Advances in Petroleum Chemistry* series, is the inclusion in this latest volume of a lengthy chapter on "Nitrogen Fertilizers", by S. Strelzoff and L. H. Cook: this is an excellent summary of the subject which deserves a wider audience than it may perchance attract. R. S. Egly and E. S. Starkman give us a general outline of the nature, production and uses of nitroparaffin fuels, while this volume, and hence the present series, is brought to a conclusion by consideration under the group heading "Mechanical Equipment" of "Engine Fuel Additives", by M. R. Barusch and J. H. Macpherson.

The high-level theoretical and practical purpose of this series and its execution during the years are unquestioned. The present editor and his advisory board deserve praise for their persistence, and sympathy in that this ambitious project has had to be abandoned 'midstream', so to speak. It may later on be revived in another context; but I suggest that a far wider appeal would be satisfied by the inclusion of more authors of international fame (in four of the volumes, including this present one, taken at random, only five are other than American, out of a total of 65 contributors); and that the price bracket be favourably reassessed so that many other technologists, besides university and oil company libraries, may benefit from the wisdom this series purports to dispense. H. B. MILNER

CHEMISTRY 1830 TO 1963

A Hundred Years of Chemistry

By Prof. Alexander Findlay. Third edition revised by Trevor I. Williams. (University Paperbacks, No. 115.) Pp. 335. (London: Methuen and Co., Ltd., 1965.) 25s. net.

TO quote Dr. Williams's preface to the present edition of *A Hundred Years of Chemistry*: "It is hoped that this revised edition will serve the same purpose as its predecessors, to show that modern chemistry is firmly rooted in the past and to present the subject as the product of a process of continuous evolution".

The progress of chemistry in the period covered by this book (roughly 1830–1963) has been immense. Prof. Findlay himself was born only five years after Mendeleef and Lothar Meyer's discovery of the Periodic Law, and only nine years after Kekulé postulated the hexagonal structure of benzene. In revising the 1947 (second) edition, Dr. Williams had the task of extending the range of the book by nearly twenty years, and wisely chose to "indicate some of the main lines of advance and the more important results obtained", rather than to attempt to deal comprehensively with recent developments. His work has been successful, and the book now includes such recent developments as isotactic polymers and the synthetic herbicides based on dipirydyl. In view of the vast research and development expenditure from public funds on atomic energy and nuclear weapons, and their profound political significance, it is disappointing that in the chapter on "Radioactivity and Atomic Constitution" the atomic bomb is only mentioned specifically in a footnote reference, and the hydrogen bomb not at all. The chemistry involved in rocket propulsion and space travel, too, is a subject of which to-day's readers might justifiably expect a mention. There is some evidence that the authors found difficulty in deciding on the likely level of scientific knowledge and interest of their readers: for example, a reader interested in referring to Volume 8 of *Bihang till Kongl. Vetenskapsakad. Handlingar* would know already that photography "plays a part of great importance in the life of all peoples".

The book contains about 800 footnotes, most of which are references to the original publication of important nineteenth-century contributions to chemistry, and these will be valuable to readers wishing to extend their knowledge of chemical history. At the end of the book there are about seventy "Short biographical sketches of those, now dead, who have contributed most conspicuously to the work of building . . . the present day edifice of chemistry". The choice of some of the lesser known chemists will delight Scottish readers.

Some minor criticisms do not alter my opinion that the book, as a whole, fully justifies the publisher's claim to being "an invaluable and readable history", and it is to be hoped that the success of this edition will encourage Dr. Williams to make other revisions of this excellent book in the future.

R. G. PARTINGTON

TWO STEREOCHEMICAL KEYS

Optical Rotatory Dispersion and Circular Dichroism in Organic Chemistry

By Pierre Crabbé. (Holden-Day Series in Physical Techniques in Chemistry.) Pp. xv + 378. (San Francisco, London and Amsterdam: Holden-Day, 1965.) 12.95 dollars.

OPTICAL rotatory dispersion and circular dichroism are two techniques that depend on the interaction of polarized light with matter. Together they constitute a unique tool for investigating the chirality of molecules or (to use a more everyday expression) for distinguishing between a chemical right hand and a chemical left hand. In a more general sense, they may be considered as two keys for unlocking stereochemical problems.

Until the development of commercial instruments, these techniques were the preserve of those who were able and willing to build their own equipment, and the techniques could not therefore become routine tools for the structural chemist. The appearance of commercial instruments for optical rotatory dispersion in the United States in 1953 and for circular dichroism in France in 1960 has changed the situation dramatically; for all chemists working with optically active materials (organic, inorganic or polymeric) these techniques are now of great and growing importance. The instruments, although commercially

available, are still in an early stage of development and are not yet in very wide use. The potentialities of the two techniques are therefore still not fully developed.

The rapid developments during the past ten years have been due to fruitful collaboration between three different types of worker (although some might wish to be classified under two or three headings). These are (1) the designer and manufacturers of instruments; (2) the theoretical workers; and (3) the workers who collect experimental data. In a field of study which is still in a considerable measure empirical, the services of the last-mentioned group (to which I should certainly be allotted by my colleagues) are very necessary for the further development of the subject. The lack of rapid progress before commercial instruments became available was essentially due to the fact that theoretical workers had no large body of data with which to test their ideas.

Two standard books on these topics have previously appeared: Djerassi's book on *Optical Rotatory Dispersion* in 1960 and the book by Velluz, Legrand and Grosjean on *Optical Circular Dichroism* in 1965. Dr. Pierre Crabbé—who has been associated with two of the leading workers in the field, Prof. G. Ourisson in Strasbourg and late Prof. Carl Djerassi in Stanford and Mexico—has produced an excellent overall picture of both techniques from the point of view of a structural organic chemist. Although the techniques are applicable to all types of dissymmetric structures, they are chiefly of value to the natural product chemist or biological organic chemist, since nearly all natural products are dissymmetric.

After a brief but adequate theoretical and technical treatment (Chapters 1–3, 29 pp.), Dr. Crabbé outlines in Chapter 4 (22 pp.) the types of problem to which optical rotatory dispersion and circular dichroism can give useful answers; these are, first and foremost, absolute configuration, relative configuration, location of functional groups and preferred conformations.

Dr. Crabbé then considers the chromophores which have optically active absorption bands and hence give rise to Cotton effects; these chromophores may be divided into two classes: (a) symmetrical chromophores, which are perturbed by dissymmetric environment, and (b) inherently dissymmetric chromophores.

Chapters 6 and 7 (108 pp.) deal in great detail with the saturated carbonyl group, which has proved hitherto the most profitable single field for study. Chapter 11 (67 pp.) deals with the other perturbed chromophores, among which carboxyl and related groups, aromatic functions and the nitro group are becoming increasingly important and have indeed been investigated intensively since the book was published.

Chapters 8, 9 and 10 deal with the inherently dissymmetric or 'twisted' chromophores; these include biaryls (11 pp.), conjugated dienes (13 pp.), and the unsaturated ketones (53 pp.). The amount of the space allotted to the last-named group reflects their importance.

In Chapter 12 (17 pp.), polypeptides, proteins and nucleic acids are considered. Here the optical rotatory dispersion and circular dichroism techniques are especially valuable for the investigation of helical forms—and with the present rapid development of biochemistry any method for studying natural macromolecules can be sure of extensive use. There is a final appendix on the automatic processing of circular dichroism data.

Optical Rotatory Dispersion and Circular Dichroism in Organic Chemistry contains exhaustive references to work in the field, which are especially valuable at a time when optical rotatory dispersion and circular dichroism data are appearing in many structural papers; the references include many to work in the press. The book is well printed with numerous structural formulae and diagrams of optical rotatory dispersion and circular dichroism curves which are all models of clarity. Many well-prepared tables illustrate the value of the two techniques in structural problems and emphasize the striking differences

ften found between the curves for compounds differing only in one stereochemical feature.

The publishers and printers are to be heartily congratulated on the speed of production; the preface is dated December 1964, and the book was published in April 1965.

The subject is developing vigorously and the next few years will undoubtedly see rapid extensions of both techniques to shorter wave-lengths and to other functional groups, studies of conformational equilibria and solvation—and also (though this is perhaps a more speculative field) studies on magnetic optical rotatory dispersion and circular dichroism, that is, the production of what might be called 'artificial' optical rotatory dispersion and circular dichroism curves, by the application of powerful magnetic fields to otherwise symmetric molecules.

It cannot be claimed that optical rotatory dispersion and circular dichroism will ever play a part in as many fields of organic chemistry as some other widely used techniques (ultra-violet, infra-red, nuclear magnetic resonance and electron spin resonance); none the less, their place in the tool kit of the modern organic chemist is now certain. The book will provide a stimulating guide to anyone wishing to enter the field, or wishing to see how these techniques might help his research. Those working in the field will certainly have the book already.

W. KLYNE

CLASSICAL OPTICS

Mathematical Theory of Optics

By Dr. R. K. Luneburg. Supplementary Notes by M. Herzberger. Pp. xxx+448. (Berkeley and Los Angeles: University of California Press; London: Cambridge University Press, 1964.) 105s. net; 12.50 dollars.

MATHEMATICAL *Theory of Optics* originates in a collection of notes for a course of lectures given in 1944 by the late Dr. R. K. Luneburg at Brown University. It replaces mimeographed notes issued later by the University, and since the author did not often publish his work in the journals, the present book is one of the few means of access to his rigorous and original approach to the mathematical theory of optics.

Geometrical and diffraction optics have usually been treated as quite separate fields, and often in developing them little reference has been made to electromagnetic theory. In the first chapter of his book, Luneburg shows the way in which, by considering the propagation of electromagnetic discontinuities (wave-fronts), one is led, through the characteristic equations of Maxwell, to the identification of orthogonal trajectories of such discontinuities with light rays. He notes that the possibility of deducing the principles of geometrical optics in this way is not so much because they are inherently contained in Maxwell's equations but rather that in any event only a few of the general premises of a wave theory are necessary for this deduction. In this treatment the laws of reflexion and refraction, Huyghens's construction, Fermat's principle, and Fresnel's formulae appear in discussion of the transport of discontinuities through media of discontinuous optical properties, and not, as is more usual in the case of the latter, by the consideration of the transport of monochromatic periodic waves of small wave-length.

Two chapters are devoted to Hamilton's theory of geometrical optics, a derivation of the characteristic functions, and some instructive applications of this theory to special problems. Among the latter the theory of Cartesian ovals is discussed. There are a number of interesting examples of systems such as Maxwell's fish eye in which refractive index is a function of radius alone, and some formulae relating to the final correction of systems by aspheric surfaces are derived. Included, also,

is a detailed analysis of the 'Luneburg lens'—a lens of varying refractive index which images two spherical surfaces on to one another stigmatically. This type of system has, of course, been used for micro-wave antennae. Discussion of geometrical optics is completed by two further chapters on first and third order theory.

In a chapter on the diffraction theory of optical instruments, expressions are derived for the propagation from a periodic dipole, and for the resultant diffraction patterns near the focus of perfect and aberrant wave-fronts. Following consideration of the resolution of self-luminous and non-self-luminous points, there is a discussion of the effect of controlling the pupil function. This leads, for example, to the conclusion that while the contrast of the diffraction image of a periodic structure can be improved by apodizing, the resolving limit cannot be improved in this way. This latter work by Luneburg is among the first of its kind.

One appendix summarizes definitions and theorems of vector analysis, and in another, a vector form of the laws of reflexion and refraction developed earlier in the book is used to solve some practical problems of ray tracing through plane surfaces. From time to time throughout the book, reference is made to problems of electron optics, and at the end there is a set of supplementary notes prepared by Dr. A. Blank which deals with the associated theory of electron optics. In a second set of supplementary notes by Dr. M. Herzberger the properties of optical materials are discussed.

An advantage of this book, which perhaps stems from the fact that it is based on a series of lectures, is that there are frequent helpful digressions to prove detailed points in the analysis. This completeness offsets the scarcity of references, and in a similar way the fact that there is no index is offset by a long list of contents of what is to be found in each of the chapters, paragraphs and sub-paragraphs.

From all except perhaps the expert mathematician this book will demand painstaking study, but the rewards for this would be considerable. Despite the fact that, because of its earlier origins, modern topics such as coherence, wave-front reconstruction, and lasers are not mentioned, and that the optics of crystals and metals are not included, few will disagree with the comment by Prof. E. Wolf in the foreword, that it is a "highly original contribution to the optical literature", and one which is "by no means a compilation of generally available knowledge".

W. J. BATES

SUGAR METHODOLOGY AND DATA

Methods in Carbohydrate Chemistry

Edited by Roy L. Whistler. Vol. 4: Starch. Pp. xvi+335. 96s. 6d. Vol. 5: General Polysaccharides. Pp. xxii+463. 118s. (New York: Academic Press, Inc.; London: Academic Press, Inc. (London), Ltd., 1964, 1965.)

Oligosaccharides

A Comprehensive Account of All Known Sugars of the Oligosaccharide Class of Compounds. By R. W. Bailey. (International Series of Monographs on Pure and Applied Biology. Division: Biochemistry, Vol. 4.) Pp. vii+179. (London and New York: Pergamon Press, 1965.) 60s. net.

THE first two volumes are a continuation of the now well-known and valuable series of *Methods in Carbohydrate Chemistry* originated by Profs. Whistler and Wolfson.

The policy of these editors is to select an important technique or analytical procedure and then invite an international authority to describe concisely and accurately the best proved method for a particular operation.

In Volume 4 on starch methods, more than sixty well-known carbohydrate workers united to produce seventy-five descriptive articles, and the result is a brilliant reference book for all those concerned with this important foodstuff and industrial chemical.

There are six divisions in the book which concern the preparation of starch and starch-fractions; chemical analyses; physical analyses; microscopy; starch degradation; starch derivatives and modifications, separate methods being provided for whole and modified starches, for starch bases, starch fractions and starch hydrolysates. The well-proved methods are precisely described in a manner very easy to repeat, and important and adequate references and cross-references are provided. The physical analytical descriptions are outstandingly good. No chemist or chemical engineer who deals in any way with starch can afford to be without this excellent reference book.

Volume 5, which, for the time being at least, ends the series, is concerned with the wider field of polysaccharide chemistry and the reader is introduced to new and rapidly expanding fields of macromolecules in the polysaccharide group. Here some seventy-five authors produced eighty-seven methods. Matters dealt with are: general isolation procedures, polysaccharide preparations, chemical analyses, physical analyses, determination of molecular weight, structural methods, derivatives, esterification and deacetylation, and etherification. It is difficult to pick out parts of the book for special mention, but the section on structural methods, Section 6, which includes descriptions of the methylation techniques, periodic and other oxidation techniques, degradation, etc., is of the greatest importance. In this section an up-to-date table of properties of carbohydrate methyl ethers is of special value.

Both volumes contain a wealth of information readily available for immediate reference. The presentation and printing are of the highest standards, and the editors, the authors and the publishers must be warmly congratulated on this excellent and valuable series. The chapters are extremely well referenced and cross-referenced, and the books contain suitable general and author indexes.

Oligosaccharides, by R. W. Bailey, will be welcomed by carbohydrate chemists. The oligosaccharides consist of a few simple saccharides units joined together by glycosidic union. It is now comparatively easy to obtain these compounds and to decide their molecular structure and they can readily be given unambiguous definitive names. It is less easy, however, without giving them quite trivial names, to speak or write about them.

Prof. W. Whelan, who writes a brief introductory note in this book, invented a series of short systematic names based on trivial names, which have been adopted by the *Biochemical Journal*, and the author has made use of these names in this work. The book is mainly an informative catalogue or source book (up to 1962) of the oligosaccharides, the number of which has grown rapidly in the past decade. The many origins, whether from naturally occurring compounds or by synthesis, of the compounds are first described (Chapter 2), and then in Chapter 3 their preparation, the methods of determination of their properties and structures are given. In a further eight chapters, each of which classifies a number of related oligosaccharides into a group, the compounds are individually described with key physical properties and explanatory notes provided. Where appropriate, the properties of derivatives are also given. The author has gathered together, evidently following a tremendous literature search, a mine of information in this important field. Excellent references are provided at the end of each chapter and there is also a classified index of oligosaccharides and a general index. This book makes quite fascinating reading and is a necessity for all reference libraries.

M. STACEY

ACTIVITIES OF ENZYMES AND ENZYMOLOGISTS

Structure and Activity of Enzymes

Federation of European Biochemical Societies, Symposium No. 1, held in London on 24th March, 1964. Edited by T. W. Goodwin, J. I. Harris and B. S. Hartley. Pp viii+190. (London and New York: Academic Press 1964.) 37s. 6d.

THE Federation of European Biochemical Societies came into being in January 1964. At its first annual meeting in London in March 1964 one of the main attractions was a symposium on the structure and activity of a few selected enzymes. *Structure and Activity of Enzymes* is a record of that symposium.

Bovine pancreatic ribonuclease provided the first subject for discussion. F. M. Richards described attempts to determine which of the 124 amino-acid residues are responsible for the manifestation of catalytic activity. Ribonuclease is particularly interesting, since it can be cleaved into two fragments, the so-called *S*-peptide and *S*-protein, which are separately inert but almost fully active when mixed. This observation, and the study of the behaviour of synthetic fragments of the *S*-peptide in association with the *S*-protein, have opened up fascinating possibilities of explaining how amino-acid residues interact in a polypeptide to determine the molecular conformation and, ultimately, the biological activity. Chemical modification has indicated that two histidine residues are essential for enzyme activity, and this view is supported by the extensive kinetic studies described by A. P. Mathias, A. Deavin and B. R. Rabin. While there is disagreement about the details and uncertainty about the role of some apparently essential residues, the main features of the reaction mechanism now seem reasonably certain.

Parallel efforts to determine the amino-acid sequence of chymotrypsinogen by F. Šorm and his colleagues in Prague and by B. S. Hartley in Cambridge are reported. The substantial measure of agreement between the two schools is a welcome demonstration of the validity of the methods for sequence determination when applied to fairly large proteins. The similarity of trypsin and chymotrypsin, pointed out by T. Hofmann, has been further underlined since this symposium was held (Hartley, Brown, Kauffman and Smillie, *Nature*, 207, 1157; 1965). Although X-ray crystallography played a remarkable part in the elucidation of the structures of haemoglobin and myoglobin, it is clear from two papers that it has not yet contributed much to our knowledge of the structure of chymotrypsin.

The third section of the symposium was devoted to investigations of the active sites of enzymes, and the variety of methods used illustrates the armoury of the molecular enzymologist. The technique of inhibiting an enzyme with a selective irreversible inhibitor and then determining the site of reaction by degradative methods is exemplified by investigations on esterases (R. A. Oosterbaan and J. A. Cohen) and dehydrogenases (J. I. Harris). A complementary procedure utilized with carbonic anhydrase (B. G. Malmström, P. O. Nyman, B. Strandberg and B. Tildander) involves the use of inhibitors containing heavy atoms followed by X-ray crystallographic investigations. The final outcome of this work will be awaited with considerable interest. In contrast, the site of binding of pyridoxal 5-phosphate to muscle phosphorylase and glutamic aspartic transaminase has been investigated (E. H. Fischer) by reducing the azomethine linkage, involving the aldehyde group of the co-enzyme and the ϵ -amino group of a lysyl residue in the protein, to a secondary amine which then survived degradative studies. Present evidence strongly suggests that azomethine linkages are a common method of binding of substrates or co-enzymes to enzymes.

The final section of the symposium was devoted to haemoglobin. While this protein is not an enzyme in the sense that it catalyses a chemical reaction, it nevertheless provides a useful model of several features of enzyme chemistry: equilibrium between protein and substrate and its dependence on pH, conformational changes induced by substrate, and molecular aggregation of the protein. All these topics received attention. An unexpected result of the X-ray crystallographic studies of oxyhaemoglobin and reduced haemoglobin was the discovery that the β -chains are further apart in the absence of bound oxygen.

This is a reasonably priced book which provides examples of the techniques used in the progress made by molecular enzymologists in recent years.

D. T. ELMORE

BIOLOGICAL RHYTHM RESEARCH

Biological Rhythm Research

By A. Sollberger. Pp. xx + 461. (Amsterdam, London and New York: Elsevier Publishing Company, 1965.) 140s.

IN this lengthy book, Prof. Sollberger sets out to discuss a very wide range of biological systems, many of which appear to have little in common except their overt rhythmical nature. 'Pure' physiological rhythms, such as heart beat, are featured, with medical examples particularly to the fore. Rhythms 'with external correlates', especially those with circadian (diurnal) periodicities, occupy a central position. But photoperiodism is also included, and even population cycles are given a place.

The study of biological rhythms has gained great impetus from the comparatively recent discovery that many circadian rhythms are remarkably persistent when studied in constant laboratory conditions. When free from the phase-setting stimulus of environmental cycles of light and darkness, the period of such endogenous rhythms usually differs slightly from the 24 h solar day. But it still exhibits a striking constancy, often remaining virtually unchanged for weeks or months on end. It is this attribute that has led to the common usage of the term 'biological clock'. Clearly, one of the main goals of rhythm research is to characterize these 'clock' systems as physico-chemical entities. So far, however, only slow progress has been made in this direction. The relationships between the environmental input and the output of the various 'indicator processes' have been explored in a wide range of animals and plants. But the clock itself remains a 'black box' which has defied further degradative analysis into separate components. Indeed, its very whereabouts has remained elusive. In these circumstances it is perhaps scarcely surprising that many physiologists have turned to the construction of model systems, the most popular of which has undoubtedly been an analogue, the electrical oscillator.

A substantial part of *Biological Rhythm Research* is devoted to laying the foundations for model building. There are chapters on the elements of general cybernetics, on servo-mechanisms, on oscillators of different types and on equations of motion. This leads into extended surveys of physical and mathematical models and of oscillator control and interaction. Although the general biologist may find this exposition salutary, he would certainly wish to be informed of the precise relevance of this information in the context of biological rhythms. A critical re-assessment of the validity of the proposed analogues in the light of the wealth of existing experimental data would certainly have been welcome. Can the models be tested? Do they permit prediction? Are they only qualitative? Do they materially aid the comprehension of what must be a biochemical system?

Unfortunately, these questions are neither posed nor answered. Indeed, the results of physiological research are given very cavalier treatment. Rather few biological examples are discussed in any detail; and, as a substitute, all too many paragraphs tend to finish in a volley of references (for example, p. 138 contains some ten lines of text and 175 authors' names).

The sections on photoperiodism are inadequate. The phenomenon is never defined nor is it clearly distinguished from photo-controlled circadian processes. Whether rhythmic endogenous mechanisms play any significant part in photoperiodic time measurement is, of course, a question which is attracting considerable present-day interest. But this problem has not been considered or even recognized. The selection of material is also most unrepresentative of the whole field of photoperiodism. Yet room is found for much entirely extraneous information on photosynthesis, chromatophore systems, the perception of polarized light, etc.

Chapters are sub-divided into a series of numbered paragraphs. Continuity of thought is not assisted by the fact that the subject-matter of adjacent paragraphs is often quite unrelated. The bibliography is immense (123 pages) but is far from being comprehensive. Its usefulness could have been improved by grouping papers under subjects.

As a text on the biological aspects of rhythms this book must be accounted a disappointment.

A. D. LEES

RADIATION PRESERVATION OF FOODS

Radiation Preservation of Foods

(Proceedings of an International Conference, Boston, Mass., September 27-30, 1964.) (Publication No. 1273.) Pp. 424. (Washington, D.C.: National Academy of Sciences—National Research Council, 1965.) 9 dollars.

FOOD scientists and technologists will be interested in a new book, *Radiation Preservation of Foods*. This book contains an excellent compilation of papers on the subject of the title. The conference was divided into four sessions dealing separately with technological aspects, source facilities, wholesomeness and food legislation, and microbiology. The appendix which follows consists of further papers dealing with the present scope and directions of food irradiation research.

Irradiation of fruits and vegetables appears to be more practicable than irradiation of flesh foods, because only the surface of the structure need be irradiated to eliminate infective yeasts and moulds. This can be done with relatively low-energy radiation which would cause only the surface of the fruit or vegetable to absorb a high dose, whereas the interior would absorb scarcely any radiation. 200-250 krad is the maximum dose most fruits can tolerate without excessive injury. This level of radiation decreases the ascorbic acid content slightly but the reduction is not nutritionally significant. On the other hand, at least 175 krad is necessary for beneficial effects in most fruits. This restricted dose range may make commercial fruit irradiators difficult to build. Off-odours and off-flavours may develop and afterwards disappear on storage of irradiated fruit. After disappearance of the off-odour the irradiated fruit is often rated organoleptically superior to the unirradiated material. Strawberries seem to be the most promising fruit for radiation preservation. Similar doses to these are suitable for extending the storage life of many species of fish, but radiation sterilization of fish does not appear to be possible. Irradiated beef develops undesirable organoleptic changes to a greater extent than lamb or veal. These, in turn, are more sensitive to flavour development than pork or chicken. The order of increasing sensitivity to undesirable flavour

development is approximately proportional to the increasing myoglobin content of the skeletal muscle tissue. These effects are to some extent caused by proteolytic enzyme changes on post-irradiation storage and can be minimized by pre-irradiation heat treatment. Undesirable pigment changes made radiation pasteurization of fresh meat unacceptable.

For radiation doses up to 1 Mrad most food packaging materials already in use are suitable, but above this dose some organoleptic changes tend to develop in the food-stuff. Only metal containers are as yet suitable for sterilizing dosages but research is under way to produce a flexible pack.

In Canada a clearance has been issued allowing commercial potatoes to receive 15 krad of cobalt-60 radiation, and in the United States irradiated canned bacon has been consumed. No adverse public reports have been received about these commodities, and extensive taste tests carried out by the United States army have shown that irradiated foods are acceptable as components of normal meals.

In the United Kingdom we are still awaiting action resulting from the recommendation of the working party on food irradiation.

G. BIRCH

PHOTOBIOLOGY UP TO DATE

Recent Progress in Photobiology

Edited by E. J. Bowen. (The Proceedings of an International Congress held at Oxford, July 1964.) Pp. vii + 400. (Oxford: Blackwell Scientific Publications, 1965.) 70s. net.

THE fourth International Photobiology Congress, held in Oxford in 1964, was the largest of the series and was attended by more than 500 scientists who represent the vanguard of the many fields of research falling within the term 'photobiology'. The *Proceedings* of the Congress reflect the determined effort made by the organizers to restrict the size of the sessions and the number of papers being read simultaneously by presenting about one-third of the submitted papers in review form, rather than allowing their authors to read them individually. These reviews were made by independent 'rapporteurs' who each selected about ten papers well before the Congress and from these prepared a 45-min summary. Thus the papers could be linked and their important features brought out while sparing the audience, and the readers of the *Proceedings*, the preambles of each of the authors.

The successful application of this technique was due almost entirely to the efforts of the rapporteurs, who are both good writers and leaders in photobiology. The seven rapporteur sessions covered the topics: basic photochemistry; photochemistry of nucleic acids; visual processes; structure of light-receptors; photo-environment; energy conversion in photosynthesis; and micro-irradiation of cells. The sessions comprised a 45-min plenary lecture by a distinguished speaker followed by the rapporteur's report. The authors of the reviewed papers were then allowed a short time to amplify any important points, and thus led into a general discussion. The *Proceedings* give these sessions in full and also the reports and a few papers from the symposia on space photobiology and on skin pigmentation.

This, however, is all that *Recent Progress in Photobiology* contains, and there is no mention of the papers—the majority of those presented—which did not fall into the confines of the rapporteur sessions and so were read by their authors in separate symposia. The editor points out in his preface that authors have been encouraged to publish their work in specialist journals, but not even a list of these papers or even a complete list of participants is given. It seems unfortunate that these *Proceedings* mention less than half the activities of the Congress. It will also be difficult for an interested reader to obtain

further information on the work abstracted by the rapporteurs, since in four of their reports no references are given, and in only one report are the addresses of the authors given. The blank pages separating the sections of the book might well have been used to give outline addresses of the participants in each session.

This book is well produced and is very reasonably priced. The editor and the publishers are to be congratulated on producing it so soon after the Congress. Bearing in mind the restrictions in scope due to limiting its size, this book forms a valuable and comprehensive survey of photobiology to-day. The introductory lectures are good reviews of the seven important topics listed, and, of these, the lectures of Dr. David Shugar on the photochemistry of nucleic acids and Prof. Melvin Calvin on energy conversion in photosynthesis deserve special mention. The rapporteur reports are easy to read and, while giving a rather limited picture of present-day research, are well worth reading. The book is recommended to all scientists from physicists to physicians who are interested in the action of non-ionizing radiation on biological material.

A KNOWLES

ZOOLOGICAL MICROPALAEONTOLOGY

Principles of Zoological Micropalaeontology

Vol. 2. (International Series of Monographs on Earth Sciences, Vol. 20.) By Dr. V. Pokorný. Translated by K. A. Allen. Pp. ix + 465. (Oxford, London and New York: Pergamon Press, 1965.) 80s.

MICROPALAEONTOLOGY has for a long time played an important part in geological science, especially as applied commercially. In recent months this aspect has been brought more to the notice of people in Britain with the present North Sea drilling project for oil and gas, and in the investigation of a possible location for a Channel Tunnel.

Besides a purely commercial aspect there is in addition a considerable academic interest in the sphere of micropalaeontology. From both points of view an essential tool is a good standard text-book which combines the various groups in a more general approach than is often the case in the specialist publications.

For some years now, the German edition of Pokorný's *Principles of Zoological Micropalaeontology* has been available as virtually the only book in its field. The English translation of these two volumes (of which the book under review is the second) has long since been overdue and should now prove, to an even greater extent, to be a valuable work of reference to students and professional workers alike.

Pokorný has provided in the two volumes a complete work on all aspects of zoological micropalaeontology and is to be congratulated on a first-class piece of work. Because *Principles of Zoological Micropalaeontology* is a straightforward translation of the 1958 German edition, certain aspects of the work are now slightly out of date. However, considering the pace with which scientific thought progresses these days, surprisingly little has been really affected.

The treatment, in the first three chapters, of the Porifera, Octocorallia and Scelcodonta indicate from the start the wealth of information to be found throughout this book. This is certainly true for the conodonts, which are dealt with in some detail. One point I should like to elaborate on here is the separation by Pokorný of the conodonts into two distinct groups, lamellar and fibrous. This distinction is not at present recognized, since a transition between lamellar conodonts and those showing a secondary fibrous state has been observed within a number of individuals.

The major part of this volume is devoted to a detailed study of the Ostracoda, a group which is becoming increasingly important. This section is introduced by a lively and informative consideration of ostracod morphology, ecology and evolution, together with a historical résumé of the classification. A common misunderstanding among palaeontologists is to suggest that the two ostracod valves are connected along the hinge margin by an elastic ligament. No such structure has yet been observed in living species. This idea of an elastic ligament is put forward in several places by Pokorny without further explanation, and all one can suggest is that he is regarding the outer chitinous layer of the carapace which passes over the hinge as having elastic properties in that region. Again there is no evidence of this.

The major part of the ostracod chapter is devoted to a detailed systematic description of a large number of genera. Here Pokorny has given the lead in raising the Ostracoda to the rank of sub-class and in re-introducing G. W. Muller's grouping (1894) of the Podocopa with the Platycopa and the Myodocopa with the Cladocopa, an arrangement now adopted by the majority of ostracod workers. A useful glossary in English, French, German and Russian is appended to this section. Moreover, fish otoliths and echinoid and crinoid skeletal remains, constituents of many microfossil samples, are considered in the final chapters of the book.

The author has produced an informative volume which is the result of much original thought. The reference section at the end will be especially appreciated by those wishing to take their studies further. One serious omission from this book, in my opinion, is a generic index. This is really essential when dealing with a large group like the Ostracoda.

On the production side, Pergamon Press have produced a book of high quality containing a wealth of illustrations, the reproduction of which is extremely good. Printing errors are rare and unimportant.

Pokorny's text-book is still the best in its field and is to be recommended to all who work with microfossils.

R. H. BATE

CHEESE

Cheese

By Dr. J. G. Davis. Vol. 1: Basic Technology. Pp. viii+463. 75s. net. Vol. 2: Annotated Bibliography with Subject Index. Pp. vii+275. 65s. net. (London: J. and A. Churchill, Ltd., 1965.)

FROM time immemorial cheese has been regarded as one of the most appetizing and nourishing of foods, and has been recognized as one of the best forms in which to preserve the greater part of the most nourishing constituents of milk for future use. To-day, as Dr. Davis points out in the preface to the first volume of *Cheese*, about 3 million tons of cheese are made in the world every year, and there are now probably more than a thousand different kinds. Dr. Davis has done a great service to dairy science and to the dairy industry in general in undertaking the compiling of this comprehensive work, which in all is to consist of four volumes. The first two volumes are already available, the third is to deal in detail with manufacturing methods and will be ready in 1966, and the fourth will give an account of scientific aspects of the subject and will appear in 1967.

Volume 1 consists of four parts and begins with a most interesting historical section which deals with what cheese really is, the origins of cheese-making and the development of the industry in Europe and Britain. This is followed, still in the introductory section, by a short but most informative outline of the scientific basis of cheese-making, and by a chapter on classification of cheese varieties. This classification in itself is most helpful in

these days when so many different types of cheese are readily available and when so many of them, with a great variety of names, are now made in countries other than those with which their particular types were first associated. Part 2 of Volume 1 deals with milk itself and with the importance of its physical, chemical and microbiological properties in the manufacture of cheese and how these properties affect the quality of the product. Descriptions are also given of the tests that are applied to the milk to detect abnormalities in it and of the treatment to which milk is subjected in a modern cheese factory. Since the making of cheese depends partly on the growth of lactic streptococci and its maturing partly on the development of lactobacilli, the author has dealt with the occurrence of milks that inhibit the growth of these organisms and also with the problem of antibiotics in milk.

Part 3 gives an account of the materials and the equipment used in the making of cheese. Five chapters here are devoted to 'starters', what they are, and factors affecting their preparation, behaviour and control. Another two chapters discuss the preparation, properties and use of rennet and the chemistry of the reaction which the enzyme rennin catalyses in milk. The additives that may be used in cheese-making, such as salt, annatto and other colouring matters, and materials such as wax and plastics that may be applied for protective purposes to the rind of cheese, are also very adequately discussed. At every stage in modern cheese-making scientific control is essential to ensure a first-rate product, and the methods used for this purpose are described in Part 3, which ends with a particularly informative chapter on traditional and modern equipment used in the manufacture of cheese. Finally, Part 4 gives an account of modern methods of packaging and also of the ripening and storage of cheese.

Throughout this first volume the author has maintained an excellent balance between the space he has given to descriptions of the older traditional methods, which are in themselves so interesting, and the amount of space he has devoted to modern developments such as the move towards complete mechanization of the Cheddar process, the invention of continuous cheese-making machines and the vacuum cheese presses which are now being evolved. This first volume is well illustrated with a large number of first-rate diagrams and photographs.

Volume 2 consists entirely of a list of 6,803 publications relating to cheese together with a most comprehensive subject index which alone occupies 47 pages. The references are arranged in alphabetical order according to the name of the first or sole author, and in addition to the usual information, such as date, journal and page number, a few words are added beside each reference such as "penicillin in milk and starters", "whey separation" or "gorgonzola manufacture", to indicate briefly but clearly what each paper is about. As the author of the volume rightly indicates in his preface, when this bibliography and subject index are used together it is possible to obtain in a few minutes a list of references to the literature available on any aspect of the subject. In the preparation of this volume, Dr. Davis was assisted by Miss Doris Knight, formerly librarian at the National Institute for Research in Dairying, Reading. They have attempted to cover the scientific and technical literature on cheese from the earliest times to 1961, and they have endeavoured to ensure that the period between 1940 and 1961 has been particularly well covered. Volume 4 will bring the bibliography up to date by dealing with the period from 1962 to 1966.

This bibliography and index should be of great value to research workers, dairy technologists, teachers and students and to all those whose job and interest it is to be well informed on cheese and related subjects. As the author rightly suggests, it is probably unique, and certainly it fills a gap so effectively that the pattern is one

that will surely be followed by others. The author and publishers are to be congratulated on the excellence with which these two volumes have been produced at what is in these days a relatively modest price.

J. A. B. SMITH

WHEAT

Wheat

(World Crops Books.) By R. F. Peterson. Pp. xxiv + 431 + 77 plates. (London: Leonard Hill Books; New York: Interscience Publishers, Inc., 1965.) 95s.

WH^{EAT} is the thirteenth in the *World Crops Books* series and follows the pattern of its predecessors in providing information on every aspect of significant knowledge from chromosomes to world trade. The objective is, to say the least, ambitious although the intention is stated to be only to give a "broad outline of the botany, cultivation and utilization of wheat" and to provide for the student a general introduction to wheat. For the specialist it is a reference book providing a guide to reading outside his speciality, and the text is supported by a subject index of fourteen pages for this purpose. It would have been impracticable to have given anything like a reasonably complete coverage in the bibliography of so wide a field of subjects as is dealt with in the book, and the relevant eight pages can only be regarded as a limited guide to what is probably the most extensive literature on any single crop.

Dr. Peterson, who is head of the Cereal Rusts Section of the Agricultural Research Station, Winnipeg, deals with his subject in nineteen chapters occupying 371 pages of text, and there are three appendixes of tables and a useful glossary. In planning a book which attempts such a complete picture of a crop it is obviously difficult to decide on an acceptable balance of subjects, and the final decision is important in giving the book its character. The author lays the greatest emphasis on the botany and general biology of wheat, including breeding and disease resistance, devoting 177 pages to these basic aspects of wheat. He then deals with the cultivation and handling of the crop in 59 pages, the grain and its utilization in 30 pages, and economic considerations with a similar allocation of space. The book is copiously illustrated by 77 photographic plates, some in colour; 46 text figures as diagrams and maps; and 36 tables. These various aids to the text are well chosen, the photographs being very good and the figures clear and explicit.

Of equal importance in gauging the value and use of such compendious volumes is the coverage of the individual subjects included and the technical and scientific level of treatment. The publishers have produced this book for the general reader or the student of agriculture, while providing a reference book for the specialist. The result is that much of the text dealing with the botany, for example, has to be at an elementary level and includes information that can be found in a number of standard books on agricultural botany. The genetics and cytology are similarly treated, starting with the cell and cell division. The author does manage to bring to a focus the most recent information and interpretation of such matters as the cytogenetics of wheat, however, and this achievement is valuable for the student and general reader. But the overall treatment does mean that it has been thought necessary to include a considerable number of elementary figures such as illustrations of plant cells and figures depicting mitosis and meiosis.

The situation is realized by the author, who remarks in the opening to the chapter on achievements in wheat breeding: "A full account . . . would require several volumes written by workers familiar with the details of the various breeding programmes". He deals with the subject in 37 pages, with 20 lines devoted to the United

Kingdom and just over 7 pages to the North American continent. It might also be commented that it is virtually impossible, in my opinion, to deal satisfactorily in 19 pages with the objectives, methods and organization of wheat breeding on a world basis. It would be easy, for example to quarrel with Dr. Peterson's allocation of space and treatment of such subjects as the induction of point mutations, hybrid wheat and plant breeding by "directed training" according to the precepts of T. D. Lysenko.

However, to produce a book of this kind is a considerable task, and Dr. Peterson has succeeded in writing lucidly and attractively on a wide range of topics to provide a useful addition to the series on world crops under the editorship of Prof. Nicholas Polunin. It would be difficult to find comparable information on wheat without consulting a number of books or even original scientific papers, and, no doubt, many enquirers on wheat topics will be most grateful for this contribution. G. D. H. BELL

WEST AFRICAN FLOWERING PLANTS

Introduction to the Flowering Plants of West Africa

By M. Steentoft Nielsen. Pp. ix + 246. (London: University of London Press, Ltd., 1965.) 42s.

AT a time when education in all the West African countries is surging ahead, suitable text-books must be in great demand. Perhaps of all scientific subjects, biology requires books specially written for each area of the world. West Africa is now served by several botanical works which should stimulate interest in the native plants of the region; this is a pre-requisite for an understanding of the need to conserve the natural flora and for its most suitable utilization.

Mrs. Steentoft Nielsen begins the work in a conventional way for a botanical text-book by describing the morphology of an easily obtainable plant: the cowpea. (It might be mentioned that as the cultivated plant has been selected the name *Vigna sinensis* rather than *V. unguiculata* would have been more appropriate.) A useful chapter deals with morphological modifications and adaptation using West African—although not always common—examples. Other chapters tackle classification and ecology, while a large one is devoted to an analysis of West African vegetation. It is based appropriately on the classification of vegetation types used in the *Vegetation Map of Africa*, published by Association pour l'Étude Taxonomique de la Flore d'Afrique Tropicale in 1958. A curious feature of the ecological section is the frequent digression in the text by the author to provide a morphological description of an important species not described elsewhere.

More than half the book is devoted to the description of 128 families in greater or lesser detail according to their "ecological importance". The same criterion is used for the selection of those genera and species discussed and described. There may be too much detail for the average student, but if his study is backed up by field work and by judicious selection by his teacher he will find the information easy to assimilate. The nomenclature and classification are based on the standard *Flora of West Tropical Africa*, using the revised edition for the dicotyledons and the first edition, with modifications, for the monocotyledons. Here and there certain statements and generalizations may be questioned, but this is almost inevitable in a work that contains so many small details, and occasionally names have been switched. The 68 figures by the author herself are a useful feature, providing the student and teacher with clear drawings of dissections and floral diagrams not easily obtainable elsewhere. However, some are rather stylized and one at least (Fig 48) has certain inaccuracies.

The publication of Mrs. Steentoft Nielsen's book is something of an event. The author (*née* Margaret Fox) herself taught at the University of Ibadan and her book should have a wide appeal to university and college students, also to school-teachers, interested amateurs, foresters and agriculturalists, who will find it a work of reference as well as an introduction to West African plants.

F. NIGEL HEPER

A SULPHURETUM OF BACTERIA

Photosynthetic Bacteria

By E. N. Kondrat'eva. Translated from the Russian by Jean Salkind. Edited by Dr. E. Rabinovitz. Pp. 243. (Jerusalem: Israel Program for Scientific Translations; London: Oldbourne Press, 1965.) 72s.

THE photosynthetic bacteria are divided into three main families, Athiorhodaceae, Thiorhodaceae and Chlorobacteriaceae; the first two are known as the purple non-sulphur and purple sulphur bacteria, respectively, and the last as the green sulphur bacteria. The Thiorhodaceae and Chlorobacteriaceae are strict anaerobes and utilize hydrogen sulphide and other sulphur compounds as a source of reducing power in photosynthesis, while the Athiorhodaceae are generally photoheterotrophes, although some are facultative aerobes and can grow in darkness.

The modern era of study of the photosynthetic bacteria began with the now classical investigations of van Niel in the 'thirties; since then these organisms have been the subject of numerous investigations relating not only to photosynthesis but also to their general metabolism. As experimental material for studies on photosynthesis, they have many advantages over the more intractable higher plants; but in one respect they, themselves, are intractable: to my knowledge no one has yet succeeded in producing satisfactorily active chromatophore fragments. Comparative biochemistry has also benefited greatly from studies with photosynthetic bacteria.

Although many excellent reviews exist on various aspects of the biochemistry of photosynthetic bacteria, Kondrat'eva's book is the first comprehensive monograph on the subject. His claim "to sum up the data concerning photosynthetic bacteria" is justified if one adds the phrase 'up to early 1962', when references cease. It can therefore be recommended as a satisfactory source book of the literature up to that time. The further aim to "provide a clearer concept of the prospects of future research in the field" is less successfully achieved because little or no critical assessment of the data is made and because, between the time the author completed his survey and its appearance in an English translation, a large number of important investigations have been reported. The topics treated include distribution, isolation, cultivation, morphology, chemical composition, physiology, photosynthesis and taxonomy. There is also a separate chapter on pigments, which have attracted the attention of chemists and biochemists for many years. There is unfortunately no subject index—presumably this was also missing in the Russian edition—and the bibliography is divided into two sections: (a) references to papers in Russian (including translations into Russian); and (b) 'others'.

Apart from a few peculiarities, such as the use of 'oxy' for 'hydroxy' and 'phenazine metasulphate' for 'phenazine methosulphate', the translation appears to be very satisfactory. A small number of obvious typographical errors were observed but errors of fact were few; the structures of farnesol (p. 88) and γ -carotene (p. 91) are, however, incorrect.

Photosynthetic Bacteria has been produced by a photo-offset technique, and while the typography is satisfactory,

one or two of the diagrams are not easy to decipher. The half-tone plates of electron micrographs are less satisfactory and one doubts if the authors who gave their 'kind permission' for reproduction of plates will feel that they have been kindly treated.

The price is high, 72s. for 243 pages, and compares rather unfavourably with the usual present-day cost of 25–30s. per 100 pages of a conventionally printed book, containing about the same number of words per page. One wonders whether the photo-offset technique is a sensible choice if the price of the final product is not considerably lower than that of a conventional book.

In summary, this is a book to be recommended for the library of any department concerned with research in photosynthetic bacteria.

T. W. GOODWIN

EVOLUTION OF STATE MEDICINE

Public Health in the Nineteenth Century

By Prof. C. Fraser Brockington. Pp. viii + 287 + 16 plates. (Edinburgh and London: E. and S. Livingstone, Ltd., 1965.) 42s. net.

PESTILENCE has always been a stimulus to public health administration and legislation. The edicts of Henry VIII, drawn up with the advice of Sir Thomas More, concerning plague and the sweating sickness, and those of Charles II and the Corporation of London on the Great Plague, are examples of this stimulus. The College of Physicians was frequently consulted as epidemics of disease were threatened or appeared. In the reign of George I, when bubonic plague ravaged Marseilles, the College appointed Dr. Mead to report, and he wrote his *Treatise on the Plague* (1720) in which he advocated a Central Board of Health with other precautions. The plague did not come to England and no action was taken on his recommendation.

In this general study of public health in the nineteenth century, Prof. Brockington first directs attention to early measures in State medicine which preceded the wider-known public health administration inspired by Southwood Smith, Arnott, Kay, Chadwick and John Simon.

Towards the end of 1804 the Privy Council consulted the College of Physicians as to how best the "Gibraltar Sickness" (an epidemic of yellow fever which had spread from Africa to Spain and killed 5,733 persons out of a population of 15,000) "might be prevented from extending its malignant effects, and what was proper and material to be known by the public at large on the subject of infectious complaints". The College promptly replied, arguing the case for strict quarantine together with services for early diagnosis, treatment and isolation, and a strict enforcement of the "Cordon Sanitaire". A central Board of Health was also recommended; this was set up in May 1805 with the Comptroller of His Majesty's Navy as president. It included the President and four Fellows of the College among its members. It established a centre of epidemic intelligence and made five important reports to the Privy Council. Sir Francis Milman, an active member, advocated its being made permanent, but, when the continental epidemic ceased, the Privy Council terminated the Board. "Frenzied action" was followed by torpor, until Asiatic cholera spread from India into Russia in 1830, and the College of Physicians was again consulted by the Privy Council.

A Central Board of Health was established in June 1831 with Sir Henry Hallford, then president of the Royal College of Physicians, as its president, six Fellows of the College and five Government officials. This Board was responsible for much good work. It investigated the disease, described it, advised on precautions against its spread and on its treatment, and recommended local boards of health, of which 1,200 were set up. In November

1831 the "physicians board" was dissolved through dispute with the Privy Council on the duration of quarantine. In its stead a Central Board of Health, unconnected with the College, was appointed. This Board was also short-lived and was dissolved at the end of 1832.

The local boards were zealous but lacked money to do their work, although cholera had reached Great Britain. By the middle of 1832 nearly 5,000 persons had died of cholera. The Cholera Act was passed enabling the Privy Council to make orders for the prevention of cholera; and provided that any expenses incurred in carrying out such orders should be "defrayed out of the relief of the poor of the parish, township or extra parochial place, maintaining its own poor". Still the financial difficulties of the local boards continued.

The Privy Council continued to act as a central health administration for a further 18 months and then abdicated. Public health was ignored as a permanent need. Prof. Brockington points out that these early struggles in the face of epidemics paved the way for the investigations and legislation promoted by Edwin Chadwick and John Simon which he describes in the later chapters of his book. Much new information is given about the first medical officers of health and other early workers in State medicine. There are brief biographies and portraits of some of the early public health pioneers. These essays when first published in the *Medical Officer* and other medical journals were highly appreciated, and Prof. Brockington has done well to assemble them in book form.

A. MACNALTY

PHOTOPHYSIOLOGY

Photophysiology

Edited by Arthur C. Giese. Vol. 1: General Principles; Action of Light on Plants. Pp. xiii+377. 100s. Vol. 2: Action of Light on Animals and Microorganisms; Photochemical Mechanisms; Bioluminescence. Pp. xiii+441. 107s. 6d. (New York: Academic Press, Inc.; London: Academic Press, Inc. (London), Ltd., 1964.)

AS the volume of original publications continues to expand, so does the need for comprehensive and up-to-date coverage of the principles underlying any one field of investigation. The two volumes of *Photophysiology* succeed well in doing this. Together they comprise twenty-one chapters, each a review of a particular facet of the subject, which in his preface Prof. A. C. Giese defines as the study of the physiology of the action of non-ionizing radiations—ultra-violet, visible, and infra-red—on living things. Giese emphasizes that the two volumes should be considered as an integrated whole, and indeed the basic principles outlined in the opening chapters of Volume 1 are essential background for the accounts both of the action of light on plants, which make up the remainder of Volume 1, and on micro-organisms and animals in Volume 2.

The first four chapters will be of particular value to those readers whose own research field is not photophysiology. They provide the basic theory, describe apparatus used and discuss the difficulties involved in both experimentation and interpretation. In a brief historical introduction, Giese traces the development of photochemistry and indicates the various responses of plants and animals to radiation. Most photochemical reactions are wavelength dependent and it is therefore essential for the majority of experimental investigations to have a source of high-intensity monochromatic light. In the chapter by S. Claesson, light sources, filters and monochromators, measurement of light intensity, calculation of quantum yield and flash photolysis are described. An excellent account follows of the theory of electron spin resonance by M. S. Blois, jun., and E. C. Weaver. They describe

electron spin resonance, spectrophotometers and indicate the difficulties encountered in making measurements in biological systems. A critical evaluation is made of electron spin resonance measurements in photosynthesis. A. D. McLaren discusses the photochemical effects of light on macromolecules, including enzymes, nucleic acids and viruses. Data on absorption spectra and action spectra are essential for the elucidation of the mechanism of action of radiation effects. Mary Belle Allen gives a very clear account of the problems which may arise when measurements are made using biological systems, the instruments used and the interpretation of the data obtained.

Next there are three chapters dealing with the role of light in photosynthesis. After a brief résumé of the early work which led to the demonstration of photosynthetic phosphorylation in chloroplasts, Whatley and Losada postulate electron flow mechanisms and cite experimental evidence for the occurrence and participation of intermediates. They produce a persuasive account of the one quantum—one electron transfer scheme. R. K. Clayton follows with a short but informative discussion of other possible interpretations of the Emerson effect and enhancement phenomena, and rightly emphasizes the need for an open mind until more experimental evidence is available. The 'biophysical' problems of photosynthesis, behaviour of chlorophyll *in vivo* and *in vitro*, absorption of light quanta, nature of the excited state and events at the reaction centre, form the main bulk of the chapter. L. R. Blinks then gives a concise account of the nature and role of the accessory pigments.

The four remaining chapters of Volume 1 each deal with quite different topics. Phototropism in higher plants is reviewed by W. R. Briggs. It is of interest that such a large amount of experimental work has been carried out on such a small range of experimental material. Most of the work described has been performed with either oat or corn coleoptiles. A very clear account of possible relationships between auxin and curvature, action spectra, and kinetic studies is given. H. I. Virgin brings together much useful information on such diverse topics as chlorophyll formation, chloroplast movements and protoplasmic streaming. The photochemical aspects of photoperiodicity are discussed by S. B. Hendricks, and biological clocks, endogenous daily rhythms and the modifying effects of the environment are covered in the final article by J. W. Hastings.

The first chapter of Volume 2, written by A. Wolfson, deals with animal photoperiodism. He gives a detailed description of the effects of day-length on metabolic changes, migration and reproduction in birds and briefly records facts regarding other animals. The photoperiodic response is extremely complex and the problems involved in analysing it are discussed in relation to natural behaviour and to the experimental modification of the reproductive cycle by alteration of day-length. R. K. Clayton gives a second clear account; this one, on phototaxis in micro-organisms, deals mainly with green flagellates, blue-green algae and purple photosynthetic bacteria.

The following three chapters are concerned with vision. The photoreceptor process in lower animals is surveyed by D. Kennedy, vision as a photic process by W. A. H. Rushton, and the physical limits of visual discrimination by H. B. Barlow. These are followed by a chapter by A. C. Giese, who provides a comprehensive survey of ultra-violet radiation action on animals. Action spectra, the nature of possible absorbing substances and the effect of physiological status on the types of response recorded are discussed and there is an interesting account of the use of ultra-violet microbeams to investigate effects on different parts of the cell. G. Zetterberg discusses the mutagenic effects of ultra-violet and visible light, and C. S. Rupert that strange phenomenon, the reactivation of ultra-violet light damage by visible light. For the interpretation of many of the effects on living organisms,

lucidation of the effect of ultra-violet on nucleic acids is essential. K. C. Smith provides a critical account of our present knowledge of their photochemistry and clearly indicates those areas which stand in need of investigation. The final chapter, by A. M. Chase, is devoted to bioluminescence, and here the biochemistry of the reaction in a varied collection of organisms is described.

Prof. A. C. Giese is to be congratulated on bringing together such an excellent and well-balanced selection of articles. The standard of writing and clarity of exposition are consistently high. The treatment throughout is at an advanced level and the volumes should be of interest to research workers in neighbouring fields, university teachers and senior students. The high price will unfortunately prevent many who might like to possess the volumes from purchasing them, but they should be found on the shelves of most institutional libraries.

EDITH HARRISON

THE THYROID

The Thyroid

Edited by J. Brach Hazard and David E. Smith (International Academy of Pathology. Monographs in Pathology, No. 5.) Pp. xii + 288. (Baltimore, Md.: The Williams and Wilkins Co., 1964. Distributed in the United Kingdom by E. and S. Livingstone, Ltd., Edinburgh.) 108s.

FEW organs of the human body have been the subject of such detailed and effective investigation during the past 20 years as the thyroid gland. In particular, the use of radioactive isotopes of iodine has greatly facilitated a wide range of biochemical investigation, and has made possible very many measurements of the kinetics of iodine metabolism in the thyroid gland or in different body tissues in health and in disease. The applications of radioiodine are so varied and by now so familiar that it is particularly refreshing to see a work devoted mainly to other aspects of thyroid function and pathology, of which the examination does not depend on kinetic or metabolic tracer studies, but in which progress has been equally outstanding.

For example, the examination of auto-immune processes in thyroid disease has thrown light, not only on the forms of local or general 'thyroiditis' in which they are consistently involved, and on the development of thyroid deficiency without glandular enlargement, but also on auto-immune phenomena generally in human disease. Similarly, studies of the normal pituitary control of thyroid function have failed to explain conditions of thyroid over-activity as pathological exaggerations of the normal mechanism, and the demonstration of an abnormal and long-acting stimulator replacing and over-riding the normal hormonal control is one which may have wider implications than in thyroid disease alone.

The International Academy of Pathology's monograph is based on communications presented by a number of authors at a meeting on "The Pathologic Physiology and Anatomy of the Thyroid" held in Cincinnati in 1963. The review is thus a selective one, and deals with a number of important and developing subjects, with good co-ordination of treatment and little unnecessary overlap between the work of different contributors. An excellent group of four papers deals with aspects of thyroiditis: the histological patterns associated with different clinical forms of the condition, by Woolner; the experimental production of comparable lesions, by Witebsky; the techniques of antibody identification, by Beutner; and the types of immune phenomena occurring in thyroid disease by Senhauser, based on collaborative work with Roitt and Doniach. Beierwaltes gives a useful survey of genetic factors in thyroid abnormalities, and Brown Dobyns has discussed the pituitary and other stimulator processes involved in thyroid function and disease, including the

still somewhat nebulous 'exophthalmos producing factor'. Prominence of the eyes can be due to so many different causes in different circumstances that it remains difficult to be sure of the relevance to the human condition of biological assay methods. Revealing data are given by Klinck on the distribution of normal thyroid tissue outside the anatomical gland in man, and the same subject is referred to by Gorbman in his chapter on "Comparative Pathology", which describes also the response of the gland to radiation—a subject dealt with in detail by Vickery, who discusses autoradiographic methods and artefacts with authority.

Although the papers have been developed and extended since their oral presentation, the date of the original meeting is still reflected in the references cited, of which only about 10 per cent are more recent than 1961, with only 3 per cent since 1962. Reviews do not therefore refer to recent findings such as the curious associations of amyloid-producing medullary carcinomata with pheochromocytoma, neuroma and a familial incidence of similar conditions, or the newer work on the chemistry of the thyroid-stimulating hormone and the long-acting stimulator, and the inter-relations between the circulating levels of these substances in thyroid disease.

The format and clarity of publication and illustration are excellent, with the one unfortunate exception that the very clear maps of the geographical distribution of goitre prepared by Kelly and Snedden and published in the World Health Organization monograph on *Endemic Goitre*, with goitre belts clearly shown by red hatching on grey indications of mountain areas, have been reproduced in monochrome in an otherwise admirable chapter on "Geographic Pathology of Thyroid Disease" by Scrimshaw, so that it is no longer possible to distinguish the limits or even the presence of goitre areas hatched in black on the black of mountainous regions.

The work remains an important and authoritative review of many normal and pathological aspects of thyroid function, and of techniques required in their study, and will be of value and stimulus to many whose interests are in the control of organ function and the genesis of disease.

E. ERIC POCHIN

THE EXPANDING EYE

Development of the Eye

By G. V. Lopashov and O. G. Stroeve. Translated from the Russian. Pp. 177. (Jerusalem: Israel Program for Scientific Translations; London: Oldbourne Press, 1964.) 72s.

IF there is a flaw in the last movement of the "Fifth Symphony", it is that Beethoven gave it too many endings: this book has too many beginnings. But once it reaches page 44 it cracks ahead, and it would be a grave error if one were to imagine that this is Mann's or Barber's book on ocular embryology brought up to date. In fact, the authors disclaim to have written an ordinary textbook although their book is both this and a monograph.

As a text-book it forms an approximate introduction to the subject. The student who uses it must pray that he will not be asked a question on the layers of His and Chiewitz, nor on the development of the vitreous (other students may be pardoned for whispering prayers regarding the latter question). As a monograph it offers a newly refreshing, if mechanistic, outlook on the development of the eye. Organizers have gone out of fashion, although "inducing agents" are still with it: there is no index to help you remember where exactly they are defined. But the basic idea underlying Lopashov and Stroeve's view of the expanding ocular universe is that a shove here, a little pressure there will do the trick. What makes the tissues shove, what press? Ah—that would be telling. . . . The approach enables one to understand why the embry-

onic lens is both relatively large and spherical, for it helps to stretch the retina, thus speeding its differentiation into all those layers. It is a thousand pities that this subject of embryological mechanization is not pursued as regards the bearing it may well have on the aetiology of myopia where deformation of the eyeball may be involved. In this context it is sad to report that the authors find that "accurate experimental data concerning the origin of the scleral mesenchyme is lacking" (p. 110): One also wonders to what extent birth is no more than an accident, of which the development of the eye, perhaps retarded in myopia, may not officially take cognizance. At the same time, the authors lead one to revise some older facile explanations, such as that of the transparency of the cornea on the basis that it is due to arrested embryonic development: when pigmented epidermis replaces ectoderm that would normally form a cornea, or the eye-anlage is transplanted under the abdominal dermal epithelium, depigmentation and corneal formation follow. Again, while the probabilistic approach has replaced that of predestination in general embryology, it is refreshing to see references to eye formation of greater or smaller frequency even though they are not quantified. As the probability of most tissues to form parts of eyes is almost unity to begin with but, with the exception of the chosen few, they lose it rapidly as they have other business to attend to, the study of the eye, as the authors emphasize, may be of general embryological interest. One can almost watch someone compute the odds in favour of the formation of a monster—or a thalidomide baby. Lest you think this far-fetched, conditions favouring the development of cyclopia and anophthalmia are carefully set out. It remains to be seen, however, whether the importance tentatively attributed by the authors to the blood supply in connexion with the formation of the embryonic fissure may not be exaggerated.

Now for the criticisms. The production of the book is provocative. It is printed by a lithography-cum-type-writer process so that the right-hand edges are not squared off. I welcome this if it reduces cost, for so many technical books are produced for the greater glory of their publishers; inevitably out of date in two or three years' time, such books contain Vance Packard's "built-in waste". But in this case economy went too far. The reproductions of the photographs may be acceptable to the Russian eye, but are valueless by Western standards. Moreover, it seems utterly fantastic that there is scarcely a reference to electron-microscopic studies and no photograph obtained with the electron microscope. Other anatomical writers' habit of not considering a mention of the scale of magnification *de rigueur* is regrettably shared. And why Soviet references should be segregated from the rest in a list not free from error remains to be explained. The translation is adequate even though there is some talk about 'inner ocular pressure' and 'accommodation'. Those remarks are, however, addressed to the authors. Let the reader be told that the book is stimulating, thought-provoking and definitely worth owning—for three or four years.

R. A. WEALE

CHEMOTHERAPY RESEARCH

Antimicrobial Agents and Chemotherapy—1964

Edited by J. C. Sylvester. Pp. xiii + 789. Proceedings of the Fourth Interscience Conference on Antimicrobial Agents and Chemotherapy, New York, October 26–28, 1964. (Ann Arbor, Michigan: American Society for Microbiology; London: H. K. Lewis and Co., Ltd., 1965.) 15 dollars.

ANTIMICROBIAL Agents and Chemotherapy—1964 contains many of the papers presented at an Interscience Conference in New York in October 1964. Like previous volumes in the series, it presents work which spreadeagles several disciplines, and the raw material from

which it is manufactured (as is noted in a preface by Orville Wyss) is extremely uneven. Nevertheless, most of those who are concerned with chemotherapy, whether as clinicians, microbiologists, or chemists, will find in it something of interest.

The book opens with a well-balanced article by Maxwell Finland on "New Drugs and the FDA". He directs attention to the results of two opinion polls on the new governmental requirements relating to drug safety, which appeared to show that "it was just the ones who raised the greatest fuss" (the university clinical research workers, "who don't like the idea of being regulated and restricted"). Maxwell Finland also directs attention to the important role of these research workers in attempts to improve the evaluation of new drugs and makes a plea for programmes designed to increase the supply and quality of clinical investigators in this field.

The first group of papers is concerned with the production, structures and biological properties of a number of new antibiotics, most with antibacterial activity but some with antiviral and others with antitumour properties. The discovery of several members of the lincomycin and everninomicin families provides further examples of the common finding that a new antibiotic produced by a micro-organism turns out to be one of a group of compounds which have chemically related structures.

A further section of the book deals with the new penicillins and the cephalosporins, mostly with their pharmacological properties and clinical use in man. The value of these substances in medicine is now firmly established and useful assessments are made of their clinical status. However, H. J. Simon's wish for a 'panaceamycin', with all the desirable properties of this group of drugs but a much broader spectrum of activity, including *Pseudomonas* and the fungi, is unlikely to be easily fulfilled and it is arguable that problems of drug resistance may be exacerbated in the future by the extensive use now of substances with very broad spectra of activity.

Although the penicillins are non-toxic in the ordinary sense one of their disadvantages is an ability to cause hypersensitivity reactions. There is some reason to believe that the cephalosporins are not cross-allergenic with the penicillins in man, although they appear themselves to have caused some allergic reactions. However, an article by Paul H. Bunn directs attention to the complex nature of allergic reactions to the penicillins, to uncertainty about the hapten involved in the most serious of these reactions—anaphylactic shock—and to the absence of any simple and entirely reliable test for determining whether a person will react allergically to penicillin or not. Further basic studies of the immunological problems in this field are clearly desirable.

The value of some of the new penicillins and the cephalosporins depends on their resistance to hydrolysis by β -lactamase (penicillinase) produced by *Staphylococcus aureus*. But chemotherapy by members of these groups of compounds has now been extended to Gram-negative organisms, and the production by the latter of β -lactamases, which differ from the staphylococcal enzyme, has given the β -lactamase problem a wider clinical significance. M. R. Pollock has contributed a valuable review on the enzymes which destroy penicillins and cephalosporins, including a discussion of the probable role of conformational changes in relation to some of the varying 'penicillinase' and 'cephalosporinase' activities which have been encountered with β -lactamases from *B. licheniformis* and *Staph. aureus* on combination with antibody. He has also considered the different approaches which may be made, in theory, to the β -lactamase 'threat' to chemotherapy.

Antineoplastic antibiotics are discussed in a series of five papers. S. A. Schepartz gives a brief account of the activities of the U.S. Cancer Chemotherapy National Service Center, established in 1955, which has evaluated more than 120,000 fermentation broths and 20,000 plant

extracts in transplanted rodent tumour systems. Five fermentation products reached clinical trial and two of them, mithramycin and a quinone, streptonigrin, have shown reproducible activity against certain human tumours. Although the results of the programme so far are described as encouraging there appears to be no strong reason as yet to expect that the systematic screening of natural products will uncover substances which can do more than cause temporary remissions. Nevertheless, until other approaches to the cancer problem show greater sign of success a strong case can be made for extensive support of this one.

The remainder of the book contains a section concerned with the mode of action of antibiotics, including a paper on the effect of vancomycin on cell wall synthesis, and a variety of communications on subjects ranging from the increasing resistance to penicillin of the gonococcus to the quantitative estimations of antibiotics separated by thin-layer chromatography. The book is not one in which the reader will expect to find major contributions to the scientific basis of chemotherapy; but it brings together a great deal of useful information.

E. P. ABRAHAM

SYNTHÈSE MANQUÉE

Human Senses and Perception

By Prof. G. M. Wyburn, Prof. R. W. Pickford and Prof. R. J. Hirst. Edited by Prof. G. M. Wyburn. Pp. xii + 340. (Edinburgh and London: Oliver and Boyd, Ltd., 1964.) 45s.

THE authors of this unusual book occupy respectively the chairs of anatomy, psychology and logic in the University of Glasgow, and their avowed aim is "to make readily available within one cover the kind of information that a biologist, psychologist or philosopher might wish to have concerning those aspects of the subject outside his special interests". This is a praiseworthy intention, but one notoriously difficult to translate into practice. How well have the authors succeeded?

Prof. Wyburn provides an excellent outline of the anatomy and physiology of the senses along standard text-book lines. It is clearly written, agreeably up to date, and pitched roughly at the level of a first-year university course. While it would do excellently for budding biologists or medical students, one may be allowed to wonder whether it will prove so satisfactory for the students of philosophy or psychology for whom it is presumably intended. Already on p. 7 the author deals with decremental and non-decremental electrogenesis in the nervous system, which might be expected to scare the life out of any but the most intrepid philosopher. He does not seem to appreciate that students of philosophy or psychology, however intelligent they may be, seldom understand matters so elementary as basic physical units or the nature of the cell. While quick to acquire (and even quicker to question) scientific information, they have to be inducted into a whole new way of thinking. Indeed, what is really needed is a presentation of sensory physiology designed for highly intelligent scientific idiots. But this is no doubt crying for the Moon.

Prof. Pickford has an easier time, for what he has to say is, by and large, understandable to both biologists and philosophers. He deals almost wholly with experimental psychology, particularly in its application to vision. Yet a little more editorial bridging would have been a great help. Prof. Pickford's point of view is that of the traditional psychologist, concerned to delimit the conditions of perception with scant regard to its anatomical and physiological substratum. Yet psychophysiological bridges do nowadays exist, in neurophysiology, in clinical neurology and even in the applications of information theory to the analysis of sensory processes.

A little more recognition of their existence might well have caught the imagination of the young biologist or medical student, so often keenly interested in psychology but so often defeated by its seeming lack of coherence with the disciplines he understands.

Prof. Hirst's contribution is a straightforward essay in the philosophy of psychology. While incompetent to assess its technical merits, I believe that it has much to teach physiologists and experimental psychologists, prone as they are to flounder in quasi-philosophical bogs of their own making. Philosophy, it is true, cannot solve their problems, but some acquaintance with philosophical method may well sharpen argument and prevent much fruitless discussion. For the bright science student with an interest in perception, this account of the philosophical issues involved has much to commend it.

While *Human Senses and Perception* should have considerable value, and does to an appreciable extent justify the intention of its authors, it cannot be said to provide even the hope of a synthesis in the study of the human senses. Indeed, it is not even what is fashionably called 'inter-disciplinary'. There is no suggestion that any of the authors, in deploying his own expertise, has been influenced in the slightest degree by that of his colleagues. Perhaps this was intentional but it might seem the waste of an unusual opportunity. For all the many and varied merits of this book, those in search of a synthesis must still be advised to read their Helmholtz.

O. L. ZANGWILL

AGEING IN EASTERN EUROPE

International Conference on Gerontology

Edited by A. Balázs. Pp. 939. (Budapest: Akadémiai Kiadó, Publishing House of the Hungarian Academy of Sciences, 1965.) 19.60 dollars.

GERONTOLOGICAL research in Britain has progressed considerably since the third international congress was held in London in 1954. However, it is extremely unlikely that had Britain been host to another congress in 1962, it would have been able to provide nearly one hundred papers. That this was possible for gerontologists in Hungary in that year demonstrates the importance which ageing research has attained in that and other Eastern European countries. The geographical region from which the majority of the contributors are drawn is very circumscribed. It could more rightly be described as an Eastern European congress. 94 per cent of the papers originated from Hungary, Romania, Czechoslovakia, East Germany and the U.S.S.R. This does not, however, detract from the value of the publication. In 1964 the British Society for Research on Ageing organized a one-day meeting in London to which Eastern European gerontologists were invited, with the express view of permitting British workers in this field to learn more of work in progress in Eastern European countries. *International Conference on Gerontology* provides similar facilities on a much larger scale, and, without taking into account the intrinsic worth of the individual papers, can fulfil two important functions in Britain to-day. First, it can act as a check-list of the research projects being undertaken in these countries, and secondly, it must serve as a warning that Britain has still failed to appreciate to the full the importance of the ageing problem to the extent demonstrated by other countries with far smaller national budgets.

Two factors militate slightly against the general usefulness of the book. One, a general complaint of all congress memoirs, is the restricted length of each communication. This renders the book a specialist tool since no space is available for critical appraisal of the surrounding fields. The second is peculiar to the origin of the book. Nearly

8 per cent of the papers are in Russian, and for those whose linguistic attainments do not include this language neither summaries nor even title are included in any other.

The book is divided into three sections dealing broadly with the biological, medical and sociological aspects of ageing. It would, I think, be invidious to comment individually on selected papers, and the general impression given by the three separate sections may be of more help to would-be readers.

Although the biological section ranges from botany to palaeo-pathology, the main accent is on vascular changes, where the involvement of proteins, polysaccharides, lipids and hormonal secretions is considered.

The geriatric section is, as might be expected, much more varied in its approach, ranging from general questions of the care of the aged to specific topics and specific conditions which require particular control in aged subjects. For British geriatricians it is unfortunate that this section contains the highest proportion of papers in Russian.

One or two of the papers in the sociological section present studies which are peculiar to Hungary or to ageing in a socialist republic, but the majority touch on problems which are of universal interest. In this section in particular, I, as a biochemical gerontologist, found the shortness of the papers most frustrating.

In general this is a mammoth publication which should serve as very good general reading for all those concerned in similar work. It is only to be deplored that three years have elapsed between the congress and its publication.

DAVID A. HALL

THINKING BROKEN DOWN

The Pathology of Thinking

By B. V. Zeigarnik. (The International Behavioral Sciences Series.) Translated from the Russian by Basil Haigh. Pp. xvi+211. (New York: Consultants Bureau, 1965.) 12.50 dollars.

TO those who imagine contemporary Russian psychology to consist entirely of post-Pavlovian elaborations, experimental and theoretical, out of touch with the actual behaviour of individuals, this book may come as something of a surprise. Dr. Zeigarnik presents a great deal of empirical data from her investigations of the breakdown of normal intellectual processes in a variety of pathological conditions ranging from schizophrenia to arteriosclerosis, and sets them in a framework which seems to owe much to the inspiration of Vygotsky, who for a number of years exercised more effect in the West than in his native land.

In her introductory chapter, Dr. Zeigarnik accepts much from the classical German school of neuropsychiatry of the late nineteenth century, notably from Breuer, though she is perhaps rather unsympathetic and a trifle doctrinaire in stressing the dependence of its views on 'idealistic' and 'faculty' presuppositions. Her account of more recent American, German and British contributions is sometimes so compressed as to impose some distortion. But her basic point is clear. 'Classical' theories—whether they tend, on one hand, to doctrines of cerebral localization or of distinct, innate faculties, or, on the other, to cerebral mass-action or a *Gestalt* principle of function—are inadequate inasmuch as they neglect the essential characteristic of thought, which is to issue in action. It is in this latter conviction that Zeigarnik approaches the pathology of intellectual processes.

Her methods of investigation are quite largely ones similar to those used by others during the past forty years. Classification of objects, the perception of exceptions, understanding of proverbs, and the arrangement of pic-

tured events in logical time sequence are all test procedures of proved value and much used by clinical psychologists the world over. An interesting fresh element is, however, provided by the 'method of pictograms' (suggested by A. R. Luria) in which the patient is required to devise his own pictorial aids to memory for words, and the character of these aids provides data for an assessment of his abstractive capacities and tendencies.

So far as case-material is concerned, Zeigarnik has drawn her net wide. It comprises the major psychoses, traumata, vascular disease and perinatal injury and infective conditions. It is a pity that relatively little attention is paid, in any adequate statistical way, to assessment of the test results in terms of differences of pathology. But Dr. Zeigarnik's emphasis (in what is stated at the outset to be a students' text-book) is on the discernment of the main lines of intellectual breakdown regardless of its cause. These lines are three: (1) of abstraction and generalization; (2) of the logical course; (3) of the purposiveness, of thinking. That these three categories emerge so closely similar to the conclusions of other workers whose basic assumptions may have differed considerably is indeed a hopeful sign. Dr. Zeigarnik makes a contribution of considerable value, less on grounds of originality than through the admirable and fascinating way in which she illustrates her contentions by direct reference to her empirical material. Every now and then, however, her presentation seems to draw attention rather to the stereotyped character of normal behaviour adjudged 'correct' than to the true deviance of abnormal function.

It seems sad that academic Russian, at least in a field like this, apparently cannot go with any ease into simple, direct English. There is a cold didactic atmosphere about this translation which may perhaps be unavoidable, but which is notably at variance with many people's experience of conversational exchange with Russian colleagues. The book ought to be read, not only by those with direct concern with the breakdown of thought in pathological conditions but also by anyone interested in the analysis of the supposedly normal.

R. C. OLDFIELD

PHARMACY IN HISTORY

Pharmacy in History

By Prof. G. E. Trease. Pp. vi+265. (London: Baillière, Tindall and Cox, Ltd., 1964.) 50s.

MODERN materia medica is so largely concerned with defined and standardized substances that its evolution from the vegetable, animal and mineral materia medica of earlier times tends often to be overlooked. The isolation of chemical constituents from natural products and the evaluation of their biological effects, leading to the synthesis and evaluation of analogues, are relatively recent developments. It is fascinating, therefore, to recall our inheritance from earlier times and the periods of progress, stagnation and decline in medicine, science and the arts that have occurred. The history of medicine and pharmacy is not one continuous progress. It is important to be reminded of this lest we become too obsessed with the seeming miracles of modern therapy. There are many "diseases of medical progress" and many problems to be solved in the safe use of a vast and growing range of powerful therapeutic agents.

Man has learnt much by trial and error through the ages, and will doubtless continue to do so, however much scientific development encourages the planning of the trials. It is very interesting and instructive to read, in this concise and excellent monograph by Prof. Trease, of the development of pharmacy in history.

Pharmacy is concerned with medicines, and there have been many seemingly strange aberrations in its historical

development. There will, doubtless, be many more in the future.

For centuries, man has separated those plants which were good for food from those which were poisonous. That knowledge or "wortcunning" provided him with his first vegetable drugs. He learned that spices not only improved the taste of food but also had a preservative action. Extracts of both plants and animals provided arrow- and spear-poisons, and the effects of these and other poisons were noted but not understood. The preparation of drugs inevitably became associated with magic and religion and medical practice became the province of witch-doctors, priests and physicians.

Our older materia medica developed empirically from the folk medicines which were often beneficial but not dangerous. It included herbs used for flavouring and preserving food ('spices'), purgatives and remedies for expelling worms and killing lice. But it also included many preparations which were useless and unfortunately some of them are still used especially among poor people in many countries. There is undoubtedly, however, much yet to be learnt from investigation of the folk medicines of the world.

Trease briefly recounts our knowledge of ancient Egyptian materia medica, of the contributions of Greek civilization in the immediate pre-Christian era, through the investigations of Hippocrates and Theophrastus, and later, in the Roman Empire, through the work and writings of Pliny, Celsus, Dioscorides and Galen. He continues from Galen to the Middle Ages and then to the consideration of early technology and early alchemy. The development of weighing, of comminution, of pottery, ceramic and glass, of oils, perfumes and cosmetics, of sweetening agents and fermentation and of colouring matters all contributed to the development of pharmaceutical preparations. Alchemy, though particularly concerned with the transmutation of base metals into gold, was also concerned with attempts to discover the 'pill of immortality' and the 'elixir of life'. Thus it attracted many apothecaries. The words *apothēke* and *apotheca* originally meant a storehouse, but gradually came to mean a storehouse for the commodities sold by a pharmacist, and in time were applied to the whole of pharmacy. From an early date the pharmacy in Britain included areas for retail sales, for storage, and for the preparation of medicines. In medieval times drugs formed part of the miscellaneous collection of commodities known as 'spicery'. Later these were often roughly divided into the lighter, more expensive items known as 'apothecaries' wares' and the more bulky and less expensive 'grocery'. The grocers derived from the pepperers and spicers, the apothecaries from the spicers, and the chemists and druggists from the alchemists and the apothecaries. Trease re-tells the vicissitudes of the apothecaries and their long quarrels with the physicians, culminating in the Rose case of 1703-4, which had a profound effect on the subsequent practice of both medicine and pharmacy in Britain. The House of Lords found in favour of the apothecary, Rose, and against the College of Physicians in respect of the supply of medicines which had not been prescribed by any physician. Thereafter, apothecaries became increasingly concerned with the practice of medicine, and the term apothecary gradually changed its meaning from that of a pharmaceutical practitioner to that of a general medical practitioner. Although apothecaries continued to be interested in the preparation and supply of medicines, as well as in the advice of patients for a further two centuries, chemists and druggists developed separately from the apothecaries, forming their own associations. Eventually they founded the Pharmaceutical Society in 1841, and acquired headquarters for it at 17 Bloomsbury Square, London. They established there in 1842 the first School of Pharmacy in Britain.

Trease traces chronologically the development of English pharmacy against a concise background of relevant

general and social history and in so doing traces, too, the developments which have led to our modern materia medica and the widening scope for the pharmacist with the development of pharmaceutical education. The bibliographical references, the quotations from literature and the well-selected illustrations add much to the value of the book, which should appeal not only to students and practitioners of medicine and pharmacy, but also to a wider public.

FRANK HARTLEY

SCIENCE IN HUNGARY

Science in Hungary

Edited by Dr. T. Erdőy-Grúz and Dr. I. Trencsényi-Waldapfel. Pp. 316+38 photographs. (Budapest: Corvina Press, 1965.) £p.

THE Hungarian word for science is co-extensive with the German *Wissenschaft* and covers all fields of systematic study, from mathematics to musicology. The Hungarian Academy of Sciences, founded in 1825, was powerfully reorganized in 1949 under its president to this day, the eminent medical scientist Prof. István Ruzsnyák, and directs the scientific life of the whole country. It has eight sections—Language and Literary Sciences, Social and Historical Sciences, Mathematics and Physics, Agricultural Sciences, Medicine, Technical Sciences, Chemistry and Biology—but in fact its activities cover an even wider field, because it has attached to it an Institute for Musical Folklore, under Zoltán Kodály.

The present book, after an introduction by Prof. Erdőy-Grúz, contains nineteen reports by twenty-two specialists, extending over the whole vast area of sciences, with the notable exception of technology, which is represented in the excellent plates, but not in the text. This is regrettable, because Hungarian technology has many outstanding achievements to its credit, such as the flour rolling mill, the transformer, the rotary converter, the first tungsten lamp and many others. Perhaps this will be remedied in a later volume.

Hungary was long known as the greatest exporter of scientists among the small countries: of men such as v. Kármán, v. Hevesy, Bárány, Polányi, Szilárd, v. Neumann, Wigner, Teller, Szent-Györgyi and v. Békésy, with five Nobel Prizewinners among them. After 1948 the scientific leaders of the war-shaken and impoverished country made a determined effort to stop its scattering its treasures and to create the right environment for the rich native talent. The result is five universities of arts and sciences, six universities of technology and agriculture and four universities of medicine with altogether 650 departments. Even more important are perhaps the 125 independent research institutes, of which 40 belong to the Hungarian Academy of Sciences. The time is past when outstanding mathematicians and physicists, far too many for the few university chairs, had only the choice of becoming science teachers in secondary schools or of emigration.

Of the nineteen reports in *Science in Hungary*, seven can be considered as inside the field of natural science: "Physics", by Prof. Gyulai; "Chemistry", by Benedek and Kardos; "Earth Sciences", by Fülöp; "Biology and Medicine", by Törő; "Veterinary Science", by Mócsy; "Agronomy", by Koltay and Tamássy; "Mathematics", by Hajós. They all contain historical introductions on the pathetic struggles of the early pioneers, of great interest to all historians of science, rounded off by the much rosier picture of the new institutes *in statu nascendi* or already well established, and the achievements of the new men. A glance at the photographs of the new Medical Research Centre or of the Central Research Institute of Physics will give impressive proof to anybody that this small, and, by Western standards, still not rich

country has done everything for science that can be done in the way of organization. If one adds to this what one knows of Hungarian talent, there can be little doubt that these efforts must be followed by a rich harvest.

This handsome volume, in impeccable English, is not for sale through the trade, but scientists interested in Hungary may be able to obtain it through the Scientific Officer of the Hungarian Embassy, London.

D. GABOR

EARLIEST CIVILIZATIONS OF THE NEAR EAST

Earliest Civilizations of the Near East

By James Mellaart. (The Library of Early Civilizations.) Pp. 143. (London: Thames and Hudson, 1965.) 30s.

THE making of metal tools is a complicated process, more especially when the copper is derived from its sulphide ore. It would seem reasonable, then, to assume that the discoveries which led to the preparation and use of metals for tool-making purposes eventuated in only one or two places, and thence gradually spread around the world. The practice of agriculture and the domestication of animals, on the other hand, can result from climate changes and could have evolved independently in many different regions. Agriculture, especially, gave rise to the village and later to the articulated town where different groups of people performed different functions for the good of the community. Early Neolithic cultures as a rule are, therefore, more diverse in development than are the early metal cultures, and it is to the Near East that we must, perhaps, look for these earliest appearances. They succeed the so-called Mesolithic cultures which grew up following the changes of climate which took place at the end of Palaeolithic times. These in turn gave rise to a Protoneolithic period when tentative attempts at a simple agriculture and the domestication of animals can be observed. Then come the fully developed Neolithic cultures with, somewhat later, the manufacture of pottery. As has been indicated not a few slightly different developments of this true Neolithic civilization can be observed in the Near East. In *Earliest Civilizations of the Middle East* the author has described many of these for us, and the frequent illustrations, often in colour, help the reader to visualize how these early folk lived and the sort of objects they made.

In Anatolia a few naturalistic paintings and engravings have been observed which have been classed as late Palaeolithic, and, following these, there is a spread of Mesolithic cultures with typical industries including pygmy tools. One of the more evolved of these is the Natufian culture of Palestine. An illustration gives a good idea of the characteristic objects made. The protoneolithic is next considered and the succeeding chapter deals with Syria and Palestine in the seventh millennium. Here it may be mentioned that in the Near East the chronology is considerably 'longer' than has, until recently, been considered to be the case in the West. Almost certainly we in this part of the world will have to lengthen out our own Neolithic era. Succeeding chapters deal with the ceramic Neolithic period in Syria, Lebanon and Palestine, as well as in Mesopotamia and Northern Iran. Once again the illustrations are especially useful in enabling the reader to visualize the differences between the various culture groups. There follows a chapter on Anatolia where the author is very much on his own ground. Here he points out that it is a mistake to think of Anatolia as a barbarian fringe to the "fertile crescent". On the contrary, the region was a great cradle of fine Neolithic cultures. The most splendid site is Çatal Hüyük, covering some 32 acres. There are 12 successive building-levels

dating from 6500 to 5650 B.C. There are wall paintings, a rich industry including necklaces and many pottery statuettes of goddesses, etc. There is also a shrine elaborately furnished with bulls' heads. It would seem, too, that woven material was made. Çatal Hüyük was the high spot of the Near East Neolithic and after it the succeeding early metal age (Tell Halaf) seems almost to be a comedown. Nevertheless, the future, of course, lay with the spread of metal industries and the final chapter describes some of these in the area.

Admittedly the title of this little book confines us to the Near East, but it is perhaps sad to have to consider these regions, however important, without any chronological tie-up with the Neolithic cultures of Europe and elsewhere. None the less, this volume makes an admirable introduction to the subject and the author is to be congratulated.

M. C. BURKITT

ALGEBRA OF THE LATTICE

Introduction to Lattice Theory

By Prof. D. E. Rutherford. (University Mathematica Monographs.) Pp. x+117. (Edinburgh and London Oliver and Boyd, Ltd., 1965.) 35s.

A SET of elements x, y, \dots is partially ordered if there is a binary relation $x \geq y$ which is reflexive, anti-symmetric and transitive. This is a wide classification. In *Introduction to Lattice Theory*, Prof. Rutherford gives as an example, the set of all human beings, when $x \geq y$ means that either x and y are the same individual or y is a descendant of x . The idea goes back, at least implicitly, to Boole, whose algebra remained for a long time the only system in which the elements need have no numerical significance. C. S. Pierce remarked that, if an order relation exists, union and intersection can be defined as the least thing which contains x and y , and the greatest thing contained in both x and y , that is, as a least upper bound and a greatest lower bound, respectively. Schroeder cleared up some of Peirce's detail, and Dedekind directed attention to the importance of ordered sets, and lattices. A lattice is a partially ordered set such that any two elements possess both a least upper bound and a greatest lower bound; for example, the set of all positive integers when $x \geq y$ means that y is a factor of x and the bounds are then the lowest common multiple and the highest common factor.

Boolean algebra now appears as the first and still one of the most fascinating of investigated lattices. Lattices may be classified into main groups according to the various further restrictions laid on their relations, and Prof. Rutherford gives a very clear and comprehensive picture of these types, and their applications to logic, topology, geometry, and switching circuit theory. His book is meant for the undergraduate just beginning to make a serious study of abstract algebra, and is better suited for this purpose than its only competitor in English, the brilliant but somewhat highbrow volume by Garrett Birkhoff in the American Mathematical Society *Colloquium Series*. Rutherford knows that the omission of steps which would be obvious to the trained and sophisticated mathematician may cause endless trouble to the beginner; he therefore gives his proofs in full and adds a good deal of informal expository comment, providing also some sensible examples for the reader. His text has been remarkably well organized to allow him to do all this in little more than 100 pages, but, of course, it still demands, as by their nature do all texts on abstract algebra, a remarkably high degree of sustained concentration on the part of the reader. Granted this, the rewards to be obtained from a study of this live and growing field are considerable, as a pleasure in itself and as a stimulus to constructive work. T. A. A. BROADBENT

SHORT REVIEWS

God Beyond Time

by J. H. Reyner. Pp. 110. (London: Regency Press, 1965.) 21s.; 4 dollars.

GOD *Beyond Time* is a readable and interesting account of the various tenets which—largely by convention and unquestioning custom—we cherish with respect to time. It is an age-long problem, with 'Time's arrow' always facing towards the future, giving little encouragement to clear thinking as to the possible effects of time reversal and the now generally accepted principle that in certain circumstances entropy may remain constant, or even decrease.

Some of the most original parts of the work deal with states of mind commonly classed as abnormal: Mr. Reyner is sure that there is a (real) noumenal world having properties which a purely materialistic science cannot hope to reveal. It is certainly true that a subject under the influence of the alkaloid mescaline experiences visions akin to those of the biblical witnesses of the Apocalypse. But it is equally clear that these strange events are due to interference with the normal functioning of glucose in the brain: it is a matter for serious reflexion what mankind would have been like if this reaction had been different from what in fact it is.

Mr. Reyner deals bravely with the ether of space; rendered needless by the mathematics of relativity, but not thereby necessarily eliminated from the thought-processes of natural philosophers. Most probably many men of science feel that in ether physics they stand at the very frontier between the observable and the unknowable, where negative experiment may hide a world into which only metaphysics can enter, if at all. These deep waters are probed with a seemingly reverence, and a realization of the limits of the scientific method, as commonly understood.

F. I. G. RAWLINS

Science, Faith and Society

by Prof. Michael Polanyi. Pp. 96. (Chicago and London: University of Chicago Press, 1964.) 3.75 dollars; 28s.

Nature and God

by Prof. L. Charles Birch. Pp. 128. (London: SCM Press, Ltd., 1965.) 6s. 6d.

IN the second edition of his Riddell Memorial Lectures on the meaning and nature of scientific enquiry, originally published in 1946 under the title *Science, Faith and Society*, Prof. Polanyi contributes a new introduction, 'Background and Prospect'. In this he cites several writers such as W. I. Beveridge, J. Bronowski and S. S. S. Boulmin, who have published, in the interval, views on the nature of science and pursuit of discovery which overlap his own. He reiterates that we still have no clear conception of how discovery comes about and that the creative life of any community organized essentially on the line of scientific life rests on a belief in the continuing possibility of revealing truths still hidden, or, as he now refers to express it, in a belief in "the reality of emergent meaning and truth". Apart from this, Prof. Polanyi's argument for a symbiosis between thought and society leads him to insist that a general respect for truth is all that is needed for society to be free. Moreover, while he challenges the Marxist position as firmly as ever, he seems more hopeful of an ultimate *rapprochement* from the Communist side leading to a modern theory of freedom. The introduction and the original lectures are highly relevant to present-day discussions on the organization of science and on planning in general in Britain. It is

from this pragmatic point of view, perhaps, rather than for its contribution to the philosophy of science, that this second edition is welcome.

The book has in fact much less in common with Prof. Birch's little book than the titles would suggest. While Prof. Birch believes that the supernaturalist tradition in theology and traditional science are being driven farther and farther apart, he also believes that radical changes within science and within theology and philosophy are altering the whole traditional position. His book is an attempt to explain these changes and the new and constructive way of looking at the natural world, in the light both of science and of Christian insights, which these changes open up. He begins by reviewing the successive views of the universe from the sixteenth century to 'Darwin's century', which has a chapter to itself. A chapter on chance and purpose continues this historical exposition and this is followed by one in which he considers the modern concept of creation in the light of the concept which is based on The Bible. The essence of the book is in the final chapter on the meaning of creation in which Prof. Birch sets forth (without dogmatism) six affirmations about the nature and meaning of creation which he develops from the changes previously described. His argument is supported chapter by chapter, by lists of references which constitute an admirable bibliography. Whether or not Prof. Birch convinces his readers, he stimulates discussion and thought, and his little book should shatter complacency and dogmatism on either side.

Early Seventeenth Century Scientists

Edited by R. Harré. (Commonwealth and International Library, Science and Society, Vol. 1.) Pp. xi+188. (Oxford, London and New York: Pergamon Press, 1965.) 25s.

THE seventeenth century was a golden age in the history of science. The telescope had opened up vast new spaces in the cosmos and the microscope was revealing the infinite variety and wonder of new miniature worlds. Various academies of science were in being and, in particular, the Royal Society of London had been founded on the Restoration of the Monarchy. Galileo had died and Newton been born in the same year, 1642. On every side there was the joy in the use of eyes, ears and limbs in the study of Nature and the improvement of industry and navigation. Mathematics was becoming, to an increasing extent, both the handmaid and the language of science. The end of the Thirty Years War in Europe and the Commonwealth in England was marked with a great sense of freedom in observation, thought and invention, as well as in more trivial matters. By the study of seven scientists the authors present the state of science, both in method and in content, between 1590 and 1645.

The development of ideas of scientific method is followed through Bacon and Descartes, the development of the rudiments of biochemistry in Van Helmont, of physics in Gilbert, Galileo and Kepler, and of physiology in Harvey. Each of these men might be regarded almost as the founder of the branch of science in which he specialized, and laid the foundations on which the modern shapes of the respective branches of science were built. The "Harvard Case Books" have shown the way to a useful treatment of topics in the history of science. More important than details of the lives of scientists are the climate of thought in which they worked, their methods of working, their antecedents and advances in scientific

method which accrued from their ideas. This method allows each scientist to be studied in depth, and each biography is sufficiently long for the purpose. The contributing authors are R. Harré on Gilbert and Kepler, J. J. Macintosh on Bacon, M. Deutcher on Descartes, D. Knight on Galileo, D. Goodman on Harvey and J. Mepham on Van Helmont.

The paper-back of only 188 pages must be considered expensive when compared with other books of similar size.
W. L. SUMNER

Science in History

By J. D. Bernal. Third edition. Pp. xxvii+1039. (London: C. A. Watts and Co., Ltd., 1965.) 84s.

FOR this third edition, Prof. Bernal has almost completely re-written Part 6 of the earlier editions of *Science in History*, with the exception of the chapter on the social sciences in history. Part 7, which contains his conclusions and is entitled *Science and History*, is substantially unchanged, apart from some factual corrections bringing it more up to date and the addition of a section "Science in a Rapidly Changing World", as well as some new paragraphs dealing with, for example, the organization of scientists, information services, and secrecy: a few paragraphs have been omitted, and others, like that on science in the developing countries, revised. Apart, therefore, from the bulk of Part 6, constituting some 328 pages out of a total of 978 and containing in successive chapters brilliant reviews of the physical sciences and of the biological sciences in the twentieth century, the book is substantially unchanged, and reflects the weaknesses that have attracted criticism in the earlier editions. Prof. Bernal is too enthusiastic an exponent of Marxism for his book to be fairly described as history in any true sense: his enthusiasm leads him to make the most naive and questionable assertions as if they were generally accepted propositions. If his failure to discriminate between opinion and fact makes part of the book still misleading for the immature and less informed, the brilliance of those two chapters on the physical and biological sciences alone makes the book worth reading. The bibliography includes many references to publications since the first edition appeared in 1954. R. BRIGHTMAN

Mathematical Discovery

On Understanding, Learning, and Teaching Problem Solving. Vol. 2. By G. Polya. Pp. xi+191. (New York, London and Sydney: John Wiley and Sons, Inc., 1965.) 42s.

NO competent teacher of mathematics can afford to be ignorant of the sequence of books by Polya on the art and science of solving mathematical problems, in which the author shows how the seemingly subconscious processes of discovery and proof, as described by Poincaré and analysed by Hadamard, can be assisted and developed by conscious organization. His examples are taken from the elementary ranges of school mathematics, but they serve to illustrate how to discard blind alleys and find through routes, how to search for equivalent and possibly simpler results, how to strip away inessentials by looking at generalizations, how to acquire by experience the skill in selecting the right tool for the job. How would you set about finding the volume of the frustum of a pyramid? In the theorem that if three circles having the same radius pass through a point, the circle through the other three points of intersection has the same radius, how can we organize our knowledge in such a way as to lead us to the hinge on which the result turns? The whole book is packed with case-histories in the anatomy and psychology of mathematical discovery, chosen from simple algebra, geometry and trigonometry by one who has proved himself a master of recondite research. It should be in every school library, to be read by every teacher of

mathematics and by every pupil who aspires to a genuine knowledge and understanding of mathematics; and it will make all readers envious of those who have had the privilege of attending Polya's seminars in problem solving, given for high-school teachers at Stanford University.
T. A. A. BROADBENT

The Physics of Ice

By Prof. E. R. Pounder. (The Commonwealth and International Library: Geophysics Division.) Pp. vii+151. (London and New York: Pergamon Press, 1965) 17s. 6d. net.

ICE is a substance the properties and peculiarities of which are of interest in many fields of science and technology. Its more unusual properties can be attributed to a lack of symmetry and resulting dipole moment of the water molecule itself, which is preserved in the ice lattice. Prof. Pounder has found that the physics of ice in its broadest context is too extensive a subject to be discussed within the confines of a paperback, and, in *The Physics of Ice*, has limited himself to topics related to his own speciality, sea ice. Indeed, the "Physics of Sea Ice" would have been a much more realistic title, a fundamentals are examined only so far as is necessary for an understanding of this subject. The author is professor of physics in McGill University, which has had a research tradition in ice physics since the classic work of Barnes on ice structure forty years ago.

The first four chapters give an account of the formation, break up and climatology of sea and lake ice which will make interesting reading for sixth form students upwards. The structure of the ice depends on the meteorological conditions during its formation, and analysis of these sections in polarized light enables some deductions to be made about its history. The remainder of the book is concerned with crystallographic properties of ice, its rheology, and the influence of brine inclusions on thermal and electrical properties, is discussed at a somewhat higher level—to be easily followed by the second year undergraduate. It is a pity that the author did not lay greater emphasis in this section on the role of lattice defects in ice, in view of their fundamental influence on mechanical and electrical properties. The literature of this subject is necessarily rather scattered, and the book concludes with a list of useful references. Many of these are, however, in reports which are unfortunately difficult to obtain.

This is a book to be read by the physics student as a source of interesting problems for discussion, and to serve as a useful reference for those more directly concerned with polar research.
J. HALLETT

The Special Theory of Relativity

By Prof. David Bohm. (Lecture Notes and Supplement in Physics.) Pp. xiv+236. (New York and Amsterdam: W. A. Benjamin, Inc., 1965.) 7.70 dollars.

THE *Special Theory of Relativity* is neither a popular treatment of special relativity nor a conventional text-book but lies somewhere between the two. The author does not try to avoid mathematics in the way that a popular writer does, but on the other hand he only uses mathematics when it is essential, and relies on physical ideas whenever possible. This makes it a most satisfactory book for background reading for anyone learning special relativity. Moreover, the author brings to his subject the benefit of long experience, both in using the theory in teaching it, so that nearly every detail in the subject has a new and unexpected light thrown on it. His approach is by way of electrodynamics and the Lorentz electrodynamics. He uses the difficulty of determining when events are simultaneous in this theory to motivate the Lorentz transformation, and then he considers at length the way in which our common sense concepts of space and time have to be modified. Various applications of relativity

mostly grouped around the equivalence of mass and energy, are then considered. The setting up of the theory is taken up again in the later part of the book in terms of the perception of distant events by means of light signals (the so-called radar method or *k*-calculus). This enables him to discuss the clock paradox in a very clear manner. There is an appendix on physics and perception in which the author tries to extend to large areas of everyday life the general ideas (as opposed to specific mathematical concepts) that arise in special relativity. In some ways this part of the book is less satisfactory because less complete than the rest. In other ways it is the most interesting part because we see here a noted scientist trying to use the knowledge which he has acquired in his professional capacity to make sense of the whole world around him. The experience is a very exhilarating one.

C. W. KILMISTER

International Directory of Isotopes

Third edition. Pp. 487. (Vienna: International Atomic Energy Agency; London: H.M.S.O., 1964.) 54s.; 9.00 dollars.

THIS new edition of the International Atomic Energy Agency's *International Directory of Isotopes* is arranged in five main sections:

(1) An introductory section explaining its purpose and layout, and giving the essential information about 83 isotope suppliers (address and short description of materials and services offered). Reactor centres which will carry out irradiations are tabulated separately against their maximum neutron fluxes.

(2) An alphabetical list of 186 radioisotopes, showing which suppliers offer them and in what form. This section has more than 3,000 entries. A summary of the radioactive properties of each isotope is given (boxed so that it stands out on the page) and the various compounds, standard solutions, radiation sources, and so on are listed. Brief specifications (specific activity, dimensions) are given, but prices are not.

(3) A list of 250 separated stable isotopes, showing the degree of enrichment and quantity available from stock. There are only three primary suppliers—Harwell, Oak Ridge, and the Soviet export organization Soyuzchimexport—but several firms offer stable isotopes in the form of Mössbauer absorbers or labelled compounds.

(4) Compounds labelled with the radioisotopes carbon-14, tritium, iodine-125, iodine-131, phosphorus-32 and sulphur-35. Compounds of other radioisotopes are included in Section 2. The supplier and specific activity (in mc./m.mole) are given. There are nearly 1,800 compounds labelled with carbon-14 and 650 with tritium.

(5) Compounds labelled with the stable isotopes carbon-13, deuterium, nitrogen-15 and oxygen-18. The 100 compounds labelled with nitrogen-15 and the 40 labelled with oxygen-18 are of special interest as neither element has a long-lived radioisotope.

With this arrangement, the *Directory* admirably fulfils its purpose, to guide the research worker to the supply organization most likely to have the isotopic material he wants. It contains less detailed information than its predecessors, but it has many more entries. It will be useful for two or three years—after which it is to be hoped that the Agency will revise it again.

C. B. G. TAYLOR

Elements of Chemistry

By Antoine-Laurent Lavoisier. Translated by Robert Kerr. Introduction by D. McKie. Pp. xxxi+1+511+13 plates. (New York: Dover Publications, Inc.; London: Constable and Co., Ltd., 1965.) 3 dollars; 24s.

DOVER Publications, Inc., have published a facsimile reprint of *The Elements of Chemistry*. This is the translation by Robert Kerr, published in 1790, of Lavoisier's

famous *Traité élémentaire de Chimie*. It is unfortunate that the excellent introduction by Prof. D. McKie is limited to only 26 pages. Prof. McKie, an eminent historian of science and authority on Lavoisier, gives a fascinating account of the state of knowledge in chemistry when Lavoisier embarked on his researches, and provides many illuminating comments on Lavoisier's work which fully justify the statement that Lavoisier was the founder of modern chemistry, with the *Traité* as its first textbook.

The *Traité* itself contains the first explicit statement of the law of conservation of matter in chemical changes, the first modern list of the chemical elements, an account of the calorimetric experiments which were the foundation of thermochemistry, and an account and illustration of the apparatus used by Lavoisier in his famous experiments on the composition of the atmosphere in which he heated mercury in a confined volume of air. The illustrations in the *Traité* (there are 13 plates excellently reproduced) were from drawings by Lavoisier's wife (whom Lavoisier married in 1771 when she was aged nearly fourteen, and who later married Count Rumford).

Although a paper-back edition, the book is well printed on good quality paper and is sewn not glued.

Anyone interested in the history of science will welcome this opportunity of obtaining Lavoisier's classic. To anyone not interested, I challenge them to read Prof. McKie's introduction and remain uninterested.

ROGER PARTINGTON

Nucleotides and Coenzymes

By Dr. D. W. Hutchinson. (Methuen's Monographs on Biological Subjects.) Pp. viii+136. (London: Methuen and Co., Ltd.; New York: John Wiley and Sons, Inc., 1964.) 18s. net.

THIS addition to the Methuen monographs is very timely. It deals with matters which are central to the whole of biochemistry. Dr. Hutchinson has succeeded in encompassing the large field of nucleotide chemistry succinctly but in sufficient detail to convey the real chemistry underlying the complex molecules that come under his survey. How different this is from the situation to be found in so many larger text-books of chemistry and biochemistry. There, the structures alone of the nucleic acids, the nucleotide coenzymes and the many other classes of natural phosphate esters are considered to be sufficient for the student's understanding of their function. In this respect one suspects that this monograph will have a much wider appeal than to the undergraduate and research student body to whom it is primarily directed.

Beginning with the nucleosides and mononucleotides, the subject is developed through the nucleotide coenzymes, including those derived from thiamine and pyridoxal, to the oligo- and poly-nucleotides. At each stage the chemical and biochemical synthesis is considered, as is the function of the compound under consideration. The section dealing with the polynucleotides is short but, in the circumstances, adequate, as the book is designed as a companion to the well-established monograph on the nucleic acids by J. N. Davidson. The bibliography is well chosen to lead the student more deeply into the subject.

D. M. BROWN

Dictionary of Nutrition and Food Technology

By Dr. Arnold E. Bender. Second edition. Pp. viii+221. (London: Butterworth and Co. (Publishers), Ltd., 1965.) 47s. 6d.

THE second edition of this useful reference book provides a greatly increased collection of information. The sources of information are extended and Dr. Bender's wide knowledge of the science of nutrition and the application of nutrition to food technology allows him to give due attention to many aspects of the subject.

For the nutritionist who works mainly in the laboratory it is useful to be able to check the composition of products under their trade names, while the nutritionist concerned with the practical work of food processing or cooking may find the cryptic initials that come into scientific texts need interpretation. This is provided not only for such as ATP (adenosine triphosphate), DNA (deoxyribonucleic acid) and EDTA (ethylenediamine tetraacetic acid) but also for H.T.S.T. (high-temperature short-time pasteurization) and A.F.D. (accelerated freeze drying). The entries from 'Abalone' (a shellfish) to 'Zymotachograph' (an instrument that measures the gas produced in a fermenting dough and the amount escaping from the dough) make enlightening reading for all who have any interest in nutrition. Those who come into the field of food from the technical angle of the physicist or the chemical engineer will find help in defining unfamiliar terms.

For the merely curious there are entries like 'cibophobia' (dislike of food) or 'Dipsogen' (thirst-provoking agent). Products such as the Japanese ham and fish sausage are described. Fruits, vegetables, cereals, herbs of many countries are listed together with products commonly derived from them. Diseases due to nutritional failure are briefly noticed including coeliac disease, kwashiorkor, coronary thrombosis and cretinism. A final table gives the calorie contributions of average portions of common foods to aid the planning of a slimming diet.

In fact, this book is clearly so useful as a reference volume for many different people that it is unfortunate that the increase in size and content has involved an increase in price. This may prevent its use as a student handbook, but it should have a place on the shelf of any library that deals with nutrition. A. M. COPPING

Les Anticorps de Transplantation

Par André Govaerts. Pp. 148. (Brussels: Editions Arscia S.A.; Paris: Librairie Maloine S.A., 1964.) 250 Fr.B.

ANDRÉ GOVAERTS was the first person to report the destruction of target cells *in vitro* by sensitized lymphocytes. In this volume he describes his researches at greater length, in the form of a thesis. The introduction defines general notions of the biology of homografts and introduces us to an extensive bibliography. Though a clearly written summary, it is not always accurate—as when a proprietary brand of polystyrene dishes is described as being polyethylene. More serious, in defining immunological paralysis the author states that this is due to the persistence of depots of antigen which neutralize the antibody as fast as it is formed. But there is an accumulation of evidence, starting with a paper by Sercarz and Coons in 1959, that this is not so, and that a central inhibition, akin to that in immune tolerance, must be in operation.

The results themselves will be of much interest to both transplantation surgeons and immunologists. The *in vitro* homograft reaction by sensitized lymphocytes has now been obtained in several other laboratories. What needs further confirmation is Govaerts's observation that immune serum (inactive by itself) would greatly potentiate the action of the cells. Furthermore, cells immune to unrelated tissue (also inactive by themselves) became active when combined with antiserum specific for the target tissue. However, these lymphocytes may have had a low level of immunity to cross-reacting antigens, so it is a pity that the author did not make the control with non-immune lymphocytes. It is also of interest that an antibody was detected (by tanned cell haemagglutination) in homogenates of sensitized thoracic duct lymphocytes, where none could be found in sera from the same animals. Notwithstanding the present interest in transformation of lymphocytes to blast cells during immune reactions, the author does not mention the morphology of the active cells in his experiments. There

is an unbiased discussion, somewhat marred (as is the whole book) by too many indiscriminate references.

R. B. TAYLOR

The Freshwater Life of the British Isles

By John Clegg. Third edition. (Wayside and Woodland Series.) Pp. 352+67 plates. (London and New York: Frederick Warne and Co., Ltd., 1965.) 35s. net.

MR. JOHN CLEGG'S work has been a most useful introduction to limnology since its first appearance in the *Wayside and Woodland Series* in 1952. As a well-balanced, elementary text it has been greatly appreciated both by teachers and students. It is unnecessary here to review the text, which remains substantially the same as in the second edition of 1959.

Nevertheless, there are changes; Mr. Clegg has undertaken some extensive revisions, such as improvements in the sections on algae, bacteria and fungi, but the most noticeable differences are in the overall size of the book and in the introduction of some new illustrations. The new edition has been given a larger format (page size 8½ in. × 5½ in.) and a correspondingly bigger type face compared with the earlier pocket size, although the pagination is virtually unchanged. This allows larger plates, but many will find this new edition rather bulky to carry on field trips.

A number of colour photographs, chiefly of ecological scenes, have been withdrawn and have been replaced by eight excellent colour plates, by Mr. E. C. Mansell, that have already appeared in the author's *Observer's Book of Pond Life*. These new inclusions are plates illustrating planktonic organisms, sponges and *Hydra*, rotifers, cases of caddis larvae, beetles, water mites, frogs and toads. Among others, there are also some new black-and-white photographs of polyzoa and of the eggs of trout and amphibia. Most of the other monochrome pictures have been improved through being printed in a larger size, but a few have lost their crispness.

The value of this new edition lies in its excellent new colour plates, but those who already have the 1959 issue plus the author's *Pond Life* will find little excuse for buying this new volume. W. J. REES

Metaphysik der Naturwissenschaft

By W. Schapp. Pp. x+141. (Den Haag: Martinus Nijhoff, 1965.) 13.90 guilders.

IN *Metaphysik der Naturwissenschaft* a metaphysician seeks to communicate his thoughts over a very wide range of subjects to those whose primary interest is physics. This is by no means a commentary on natural philosophy as such, but rather a meditation on the world, as the author sees it, in terms of history and its impact on the way in which we regard phenomena. There are three main divisions: (1) criticism of cases; (2) colours and the world; (3) world, object, concept. From these the main trend can be discerned. Much of it is a kind of distillation of Einstein and Infeld's *Evolution of Physics*, even including the familiar cloud of particles constituting the 'real' table, which reminds one of Eddington. All this is by no means to be dismissed as mere playing with words; it resembles the outlook of Goethe in contemporary dress. It is significant how deeply the place of colour is envisaged in the life of mankind, without troubling about any quantitative character. (Newton was not blind to beauty, but he set about measuring—that is the essential difference.)

There is an element of the numinous here and there, which is rather charming: for example, in the introduction of thunderstorms in close proximity to a discussion of simultaneity. Nobody but a Teutonic scholar would do quite that. These are not pages to trouble the down-to-earth man of science, but they are well worth studying by anybody with the requisite time and patience.

(Continued from page 956)

various stages of development and afterwards the haemopoietic organs of pairs of opposite sex can be analysed for cell chimaerism using the sex chromosomes as markers. Recently a technique has been developed in this laboratory for the preparation of abundant, clear metaphases from various haemopoietic organs of the chick embryo^{8,9}, thus making feasible experiments of this design.

White Leghorn fertile eggs of 6–11 days' incubation were parabiosed using a modification of the technique of Hasek¹⁰. The use of a tissue bridge was found unnecessary for the production of a parabiotic union and vascular anastomosis was readily obtained by direct apposition of the chorioallantoic membranes.

After a further 7–13 days' incubation, each egg was injected, by way of the allantois, with 0.1 ml. demecolcine solution (containing 0.05–0.1 mg demecolcine according to the stage of incubation). Three hours later, parabiosed pairs were removed and sexed. Where partners were of opposite sex, cells of the thymus, spleen, bone marrow and bursa of Fabricius were prepared for chromosome analysis using a modified hypotonic citrate–air drying technique⁸. Staining was carried out in lactic-acetic-orcin and the preparations were viewed by phase-contrast microscopy.

In an additional experiment, double-yolked eggs were incubated for up to 13 days. Unfortunately, the very high mortality found in embryos derived from such eggs meant that only two pairs of embryos of opposite sex, of 11 and 12 days' incubation, were obtained for investigation. Chromosomal preparations were made from cells of the various haemopoietic organs as before.

A very high mortality was observed immediately after parabiotic union and this no doubt was due to trauma associated with the procedure. The pairs surviving to late incubation appeared perfectly normal when sampled. Although it is probable that there were histocompatibility differences between partners, no macroscopic or microscopic evidence of an immune reaction between them was found. As well as the initial operative mortality some embryos were killed by the demecolcine treatment. Unfortunately it appears that the dose of demecolcine which enables abundant metaphases to be obtained is very close to the toxic dose for the embryo. Thus only a very small proportion of the original parabiosed eggs were eventually analysed.

In Table 1 it can be seen that in embryos parabiosed at 6–8 days' incubation and sampled at 17–20 days' incubation, 14–42 per cent of the dividing cells in marrow, 19–46 per cent in the spleen and 26–50 per cent in the bursa of Fabricius are derived from the opposite partner. The percentage in the case of the thymus is much lower (0–12 per cent).

Fig. 1. Bursa of Fabricius of demecolcine-treated 19-day embryo showing a large number of metaphases (arrowed) in the lymphoid follicles. ($\times c. 900$)

In two embryos sampled at 15 days' incubation a considerable degree of chimaerism was found in the marrow and spleen of both and in the bursa of one. In a pair parabiosed as late as 11 days' incubation, chimaerism was found in the spleen and bursa; thymus and marrow were not sampled. In the twin embryos investigated, a high degree of chimaerism was found within the spleen (27–39 per cent), a low degree of chimaerism in the thymus and marrow (0–8 per cent), and no chimaerism at all in the bursa.

In order to gain some idea of the cell type being sampled for chromosome analysis, sections of spleen and marrow were examined after demecolcine treatment and it was noted that abundant mitotic figures were distributed throughout the whole tissue in both granulocytic and non-granulocytic areas. Phase contrast microscopic examination of cell suspensions prepared from these organs showed that both cell types were present. In sections of bursa (Fig. 1) and thymus (Fig. 2) it is quite clear that the overwhelming majority of mitoses are confined to the lymphocyte series. Bursal and thymic suspensions were predominantly lymphoid though a few granulocytic elements were present.

The spleen and marrow have similar haemopoietic functions during avian embryogenesis¹¹ although the spleen develops about 4 days earlier than the bone marrow. Both are sites of production of granulocytes, erythrocytes and thrombocytes, but, while the spleen is predominantly granulopoietic after an initial erythroid phase, the marrow continues to produce both types of cell throughout

Table 1

Notes: (1) In those cases where only one embryo is represented from the initial pair the partner had died following demecolcine injection. (2) No metaphases were obtained for study from the thymic tissue of three embryos and the spleens of two others.

Fig. 2. Thymus of the same embryo showing metaphases (arrowed) distributed throughout thymocytes. ($\times c. 900$)

embryogenesis. The rapidity with which chimaerism is established in both organs indicates that there is a considerable inflow of cells into them. That the spleen, but not the marrow, is highly chimaeric in the embryos derived from double-yolked eggs probably reflects the fact that at sampling (12 days' incubation) haemopoiesis is firmly established in the spleen but there are few blood-forming cells in the marrow. There is evidence that an inflow of cells to the spleen and marrow occurs in the adult animal. Thus chromosome marker investigations have shown that there is an afferent stream of cells to both organs in the adult mouse^{12,13}.

Similarly, investigations on the repopulation of thymic grafts¹⁴ and on the movement of haemopoietic cells in adult parabiosed mice¹⁵ using the T6 chromosome marker system have demonstrated an afferent stream of blood-borne cells to the thymus. The chimaerism found in the thymus of some embryos in the present investigation shows that there are cells entering the avian thymus during embryogenesis.

Considerable interest has centred lately around the bursa of Fabricius as a site of production of antibody-forming cells¹⁶ and possibly of a hormone necessary for the maturation of such cells¹⁷. Lymphoid development begins within the organ at 14–15 days' incubation with the formation of follicular structures closely associated with epithelium, and most subsequent cell proliferation occurs

within these lymphoid follicles (Fig. 1). The fact that up to 50 per cent of the dividing cells in the bursas of parabiosed embryos are derived from the opposite partner suggests that the lymphoid follicles are largely populated by blood-borne cells. The absence of chimaerism in the 11- and 12-day embryos derived from the double-yolked eggs and in one of the two parabionts sampled at 15 days' incubation is not surprising in view of the fact that at these times very little follicular development has occurred.

In summary, it may be stated that, although there is some variability both between and within parabiosed pairs, the large number of dividing cells of opposite sex found proliferating in the spleen, marrow and bursa of Fabricius of most parabionts after various periods of incubation indicates that these organs are largely populated by blood-borne cells. Chimaerism was found less frequently and to a lesser degree in the thymus. The nature and origin of the blood-borne cells remain unknown, but they could be derived from many embryonic tissues in addition to the organs studied. Thus the pancreas, kidneys and gonads are all sites of intense granulopoiesis in the late embryo¹⁷ although the avian liver, unlike its mammalian counterpart, is not a site of haemopoiesis. The yolk sac produces various types of blood cells from a very early stage of embryogenesis and is a possible source of progenitor cells. Further experiments using grafting and chromosome marker techniques are being carried out in an attempt to clarify some of these problems.

We thank E. M. McDermid, Thornber Bros., Ltd., near Halifax, for supplying the double-yolked eggs.

ORIGIN OF THE GEOELECTRIC EFFECT IN PLANTS

By PROF. MALCOLM B. WILKINS and A. E. R. WOODCOCK

School of Biological Sciences, University of East Anglia, Norwich

WHEN a plant shoot, such as the coleoptile of *Avena sativa* and *Zea mays* or the hypocotyl of *Helianthus annuus*, is placed in the horizontal position, a potential difference develops between the upper and lower surfaces, the lower becoming positively charged with respect to the upper. This phenomenon, first reported by Bose¹ and afterwards investigated in a number of laboratories^{2–10}, is known as the geoelectric effect. In addition, shoots which have been placed in the horizontal position develop an upward curvature and this geotropic response continues until they have once again attained the vertical position. The relationship between the geoelectric effect and the geotropic response is obscure, but it has been suggested^{11–13} that the former may be an essential link between the perception of a gravitational stimulus by the shoot and the induction of the upward curvature.

Recent investigations of the geotropic response of shoots have clearly shown that the increased growth rate of the lower half and the decreased growth rate of the upper half are due to the development of different concentrations of auxin in the two halves of the organ. This concentration gradient is brought about by lateral movement of auxin from the upper to the lower half of the horizontal shoot^{11,14–17}.

The present investigation was begun to determine the relationship between the geotropic response and the geoelectric effect since, from a review of the literature, it seemed to us that there was a large body of evidence which pointed to the geoelectric effect being due to the establishment of an auxin concentration gradient across geotropically stimulated shoots. This evidence can be briefly summarized: (1) The geoelectric effect has little or

nothing to do with the primary gravi-perception mechanism since it does not develop in de-tipped *Helianthus* hypocotyls⁹ which can, nevertheless, perceive a geotropic stimulus¹⁸. It must therefore be connected, if it is connected at all, to a later stage in the geotropic response system. (2) The geoelectric effect and geotropic curvature begin to develop at a similar time (about 15 min) after the onset of geotropic stimulation^{10,19}. (3) The characteristics of the induction of a geotropic response are closely similar to those for the induction of the geoelectric effect in a variety of different experimental procedures^{10,20}. The response in both phenomena is proportional to the logarithm of the stimulation time, the presentation time for each is about 2.5 min and the angle at which the maximum response is achieved for both the geotropic response and the geoelectric effect is about 130° from the vertical. Furthermore, in experimental procedures such as those of Zimmermann²¹ the magnitude of the geotropic response and the geoelectric effect undergo closely similar changes^{10,21}. These facts clearly point to the geoelectric effect and the geotropic response being released by stimulation of the same gravi-perception system. Since the geoelectric effect cannot be connected to the primary gravi-perception system for reasons outlined in (1), the evidence in this section strongly suggests that it is associated with an intermediate stage in the geotropic response system. (4) The geoelectric effect does not develop in plant tissues in which no lateral movement of auxin occurs. De-tipped hypocotyls of *Helianthus* and other plants do not develop a geoelectric potential⁹, nor do they develop a geotropic response even if they are left in the horizontal position for 14 h (ref. 18). That the lack of geotropic response is due only to the lack of auxin in the tissue is shown by the fact that a curvature develops in response to the original gravitational stimulus when the hypocotyls are restored to the vertical position and then supplied at their apical ends with indolyl-3-acetic acid¹⁸. A similar finding has been reported for the perception of a gravitational stimulus in coleoptiles of *Avena* and *Zea*²². In the case of *Avena* and *Zea* coleoptiles, however, Grahm and Hertz^{9,10} have shown that the de-tipped organs do develop a geoelectric potential. Examination of the methods of Grahm and Hertz^{9,10} reveals that they removed only 1 mm of the apex of the coleoptile about 5 h prior to beginning the electrical measurements. In this time a physiological tip would have developed^{14,15,22,23} and this would produce auxin which would undergo lateral re-distribution on geotropic stimulation of the coleoptiles, thus giving rise to the observed geoelectric potential. (5) Neither the geoelectric potential⁹ nor the geotropic response develops in *Zea* coleoptiles under anaerobic conditions. These observations agree with the view that both phenomena are due to the occurrence of lateral movement of auxin in horizontal shoots since both the longitudinal and lateral transport of auxin are totally inhibited under anaerobic conditions²⁴.

Our hypothesis that the geoelectric effect is due to the different concentrations of auxin in the upper and lower halves of the geotropically stimulated shoot is amenable to direct test by establishing in vertical shoots a lateral auxin gradient and determining whether or not this gives rise to a potential difference between the two sides of the shoot. A lateral gradient of auxin has therefore been set up in vertical sections of *Zea mays* coleoptiles by supplying the coleoptiles at their apical ends with an asymmetric source of indolyl-3-acetic acid in a manner similar to that previously used by Goldsmith and Wilkins¹⁵. This procedure has been shown to set up in the section an auxin gradient which is proportional to the concentration of indolyl-3-acetic acid in the asymmetric source¹⁵.

Seeds of *Zea mays* L. var. 'Giant White Horse Tooth' were soaked in water for about 8 h, planted in washed vermiculite and grown in darkness. Five days after planting, the coleoptiles were decapitated twice under dim red light of wave-lengths above 595 nm. A de-tipped coleoptile was then detached from its mesocotyl

by a cut made 2.5–3.5 cm below the top of the coleoptile, and transferred to the measuring device which provided support and electrical contact at the base of the coleoptile by means of agar-calcium chloride gel.

The electrode system provided a base-reference electrode in contact with the agar-calcium chloride gel. On either side of the coleoptile, contact was made by means of a flowing 5 mM calcium chloride solution to two Calomel electrodes (Pye pH reference electrodes, No. 11161). The potential of each electrode with respect to the base was measured with a 'Vibron 33B' electrometer and the output recorded on a Kipp-Zonen, '2B-Microvolt' chart recorder. The base electrode could be varied about the earth potential by a potentiometer incorporated in the circuit. The whole electrode assembly was screened at earth potential by a zinc metal cage and illuminated from above the coleoptile segment with red light of wave-length greater than 595 nm.

At the beginning and end of an experiment the two electrodes were placed with their tips in contact so that by earthing one of the electrodes the potential across the whole system could be measured. The contact potential was never found to be more than 1 mV and was usually 0.2 mV. After the initial test of the electrode contact potential a coleoptile was placed vertically in the system and the electrodes placed in contact with either side and adjusted until both were at the same distance (usually about 3–4 mm) from the top of the coleoptile segment. This contact was maintained for 10–15 min before the experiment was begun to ensure that the system had attained electrical stability. The potential difference across the coleoptile at time zero, that is the moment before the agar block or lanolin paste is applied, was taken as zero. In practice this potential difference was never more than 2 mV. Fig. 1 shows the changes in this potential with time both before and after time zero. The potential across the coleoptile was measured at 6–12 sec intervals.

An auxin concentration gradient in the coleoptile segment was established by supplying indolyl-3-acetic acid to one-half of the apical end of the segment¹⁵. For this, two carrying media were used: (1) 1.5 per cent Difco 'Bacto-agar' which had previously been dialysed for 7 days, and (2) anhydrous lanolin. Owing to the low

Fig. 1. The changes in the potential difference across vertical coleoptile segments of *Zea mays* after the application at time zero of an asymmetric supply of indolyl-3-acetic acid (0.02 per cent) in lanolin paste (curve *a*) and of lanolin paste without indolyl-3-acetic acid (curve *b*). Ordinate, potential difference across the coleoptile in mV (*A-B*). Abscissa, time in minutes before and after the application of the paste. The arrangement of the coleoptile, electrodes *A* and *B* and lanolin paste is shown in the inset diagram. Curves (*a*) and (*b*) are respectively the means of 7 and 5 individual experiments

humidity desirable for the satisfactory working of the electrode system the agar block (1 mm²) tended to dry out rapidly. This was undesirable, since the concentration of indolyl-3-acetic acid in the source would thus increase with time. In order to overcome this difficulty a paste of aqueous indolyl-3-acetic acid solution was made with anhydrous lanolin which proved to be a more satisfactory carrying medium. The concentrations of indolyl-3-acetic acid used were 10⁻⁶ M in the agar blocks and 0.02 per cent in the lanolin. Control experiments were carried out by placing the carrying medium without indolyl-3-acetic acid asymmetrically on the top of the coleoptile segment.

The development of a lateral potential with time after the asymmetric application of indolyl-3-acetic acid-lanolin paste to the top of a *Zea* coleoptile segment is shown in Fig. 1. The curve labelled (a) is the mean of 7 separate runs each carried out on a different coleoptile. During the first 8–10 min after the application of indolyl-3-acetic acid, the side of the coleoptile under the source tended to become electronegative with respect to the other side. In the mean curve (a in Fig. 1) this difference was not significant although it did occur in 4 of the 7 individual experiments. It is particularly marked in curve (a) of Fig. 2, which indicates changes in the potential difference observed in one of the experiments which contributed to the mean data presented in Fig. 1. About 15 min after the application of the indolyl-3-acetic acid, the side of the coleoptile under the source becomes electropositive with respect to the other side and the potential difference continues to increase for about 20 min. A difference of approximately 10 mV is maintained for at least a further 20 min, but by the end of this time the potential difference appears to be gradually decreasing. When lanolin paste without indolyl-3-acetic acid is applied asymmetrically to the apical end of the coleoptile segment, no significant potential difference develops between the two opposite sides of the organ. This is shown by curve (b) of Fig. 1, which is a mean of 5 individual experiments. The mean potential difference developed by the coleoptiles treated with indolyl-3-acetic acid and shown in curve (a) of Fig. 1 is significant at the 0.05 level after 28 min.

The changes in the potential difference across an individual coleoptile treated with indolyl-3-acetic acid paste and in one treated only with the carrying medium are shown in Fig. 2. These data are presented to show the stability of the potential difference, if any, across single coleoptiles.

Earlier experiments using dialysed agar as a carrying medium provided similar results, except that the agar

alone tended to cause the side of the coleoptile under the block to become about 6 mV electronegative to the other side. When indolyl-3-acetic acid was present in the block, however, the side under the block became electropositive to the other side. This potential developed gradually, beginning about 6–8 min after the application of the indolyl-3-acetic acid and becoming as much as 16 mV after 40–50 min.

The experiments described in this article show that when a lateral concentration gradient of indolyl-3-acetic acid is set up across a vertical coleoptile segment of *Zea mays*, the half with the highest concentration develops a surface potential at least 10 mV positive to that on the surface of the half with the lower concentration.

When a coleoptile is placed in the horizontal position a lateral movement of indolyl-3-acetic acid takes place from the upper to the lower half^{14–16}. This results in different concentrations of indolyl-3-acetic acid in the upper and lower halves of the tissue, and it is this difference in concentration that gives rise to the upward curvature of the coleoptile. It is now clear that the different concentrations of indolyl-3-acetic acid in the upper and lower halves of the coleoptile also give rise to the geoelectric effect. Our results confirm the large body of circumstantial evidence summarized in the introduction that the development of the geoelectric effect in shoots is due to the lateral movement of auxin in the tissue during geotropic stimulation. The geoelectric effect in shoots must therefore be regarded as a side-effect arising as a consequence of a critical intermediate stage in the geotropic response system.

The pattern of the change in the potential difference across the coleoptile with time is similar regardless of whether the auxin gradient occurs as the result of geotropic stimulation⁹ or as the result of the procedure used in this investigation. Graham and Hertz⁹ found the lower side to become slightly electronegative to the upper side during the first 10–15 min after the onset of geotropic stimulation. The close similarity in the time required for the positive charge to develop on the lower side of the coleoptiles in the experiments of Graham and Hertz⁹ and in the side under the source of indolyl-3-acetic acid in our experiments is probably fortuitous, since in our experiments this time is almost certainly a function of the distance between the apical end of the coleoptile segment and the electrodes.

Further investigation of the mechanism of the geoelectric effect in plant shoots is now in progress.

This investigation was carried out while one of us (A. E. R. W.) was supported by a Science Research Council studentship. We thank Dr. Alan Walker for many helpful discussions.

Fig. 2. Same as Fig. 1 except that the curves show the change in potential difference across individual coleoptiles supplied asymmetrically either with indolyl-3-acetic acid (curve a) or with the carrying medium without the indolyl-3-acetic acid (curve b)

ASTRONOMY

Hydrogen Content of Virgo Cluster Galaxies

INVESTIGATIONS with small radio telescopes¹ have been unable to detect 21-cm radiation from galaxies much beyond those in the *M* 81 group, at a distance of 3 megaparsecs. The uncertainties in the distances of individual galaxies, and thus in their masses, have made it difficult to compare the hydrogen content of different morphological types. There are considerable advantages in studying galaxies in one of the large clusters, for the members can be assumed to be at approximately the same distance. In the nearby groups there are no isolated elliptical or other early-type galaxies. A knowledge of the hydrogen content of these systems would be important for an understanding of their evolution, and in the large clusters there are numbers of such early-type galaxies suitable for investigation at 21 cm.

The Virgo cluster of galaxies is the nearest of the large clusters, at a distance of about 12 megaparsecs. A preliminary investigation of 18 member galaxies has been made during 1964 and 1965 with the Australian 210-ft. telescope. 21 cm radiation has been detected from eight of these, including the giant elliptical galaxy *NGC* 4472.

The most significant datum yielded by extra-galactic 21-cm observations is the total mass of hydrogen in a galaxy. When the galaxy is much smaller than the telescope beam the hydrogen mass M_H (in solar masses) is:

$$M_H/M_\odot = 3.08 D^2 (\lambda^2/A_0) \int_0^\infty T_a(\nu) d\nu \quad (1)$$

where $T_a(\nu)$ is the antenna temperature at frequency ν , D is the distance in kiloparsecs, λ is the wave-length, A_0 is the effective collecting area of the telescope.

The integration over frequency can be performed by using a band-width B wide enough to receive all the 21-cm radiation from the galaxy. If the observed antenna temperature is T_a :

$$\int T_a(\nu) d\nu = T_a \cdot B$$

In the investigation reported here, a band-width of 1.5 megacycles was used, corresponding to a velocity spread of 320 km/sec. This may not be wide enough to receive all the radiation from edge-on systems, so that the observations then yield lower limits to the hydrogen masses.

For the 210-ft. telescope an antenna temperature T_a of 0.1° K in a band-width of 1.5 Mc/s would be produced by a hydrogen mass of $2 \times 10^9 M_\odot$ at the distance of the Virgo cluster. A low-noise parametric receiver² was used, with a noise temperature of 160° K. An analogue integrator averaged the receiver output for periods of 100 sec, reducing the root mean square fluctuation to 0.035° K. The telescope was set alternately on the galaxy and on a nearby reference region. This sequence was usually repeated for 40 min or more, the errors then being reduced to below 0.016° K. In some cases the measurement was repeated with another reference region.

In the preliminary investigations the receiver has been switched between two frequencies—one corresponding to the optical redshift³ of each galaxy, the other either a band-width higher or a band-width lower. If the redshift of a galaxy differs from that adopted, the measured antenna temperatures will be different for the two reference frequencies. The higher value has been adopted in calculating the hydrogen content.

The results are listed in Table 1. The line radiation from eight galaxies is above the limit of detection, the hydrogen masses ranging from 3×10^8 to 2.4×10^9 solar

masses. The error quoted is the standard deviation of the measurement. The distance modulus of the Virgo cluster⁴ is assumed to be 30.5. The ratio of hydrogen mass to luminosity, M_H/L , is the one quantity which is independent of errors in the distance. For NGC 4116 the ratio of 0.53 (in solar units) agrees well with that found for other irregulars². For the late-type spiral systems M_H/L lies within a narrower range than found for members of nearby groups¹, with an average value of 0.14. The ratio decreases further for the early-type systems, being below 0.01 in several cases.

The total masses M_T of the galaxies have been taken from Holmberg's catalogue⁴, or estimated by assuming that the mass-luminosity ratio varies from 4 for *Sc* to 40 for *E*. For the late-type spirals the ratio M_H/M_T agrees with that found for nearby galaxies. For the giant elliptical NGC 4472 M_H/M_T is 0.0002, well below the limit for ellipticals set by the observations of M 32 (refs. 5 and 6). The other ellipticals examined are less massive and no hydrogen could be detected in them; in each case M_H/M_T is less than 0.0006.

Davies *et al.*⁶ observed the spiral galaxy NGC 4535 with the Jodrell Bank 250-ft. telescope. They found no emission at the expected velocity (1950 km/sec), but reported a signal of 0.2° K for a velocity of 1038 km/sec. They suggested that this represented emission from an intergalactic cloud. In the present investigation a search was made for emission at this velocity, taking reference points both 1° and 2° east of NGC 4535. The mean measured antenna temperature is $-0.01^\circ \pm 0.01^\circ$ K. It thus appears unlikely that there is any emission from this direction other than that associated with NGC 4535 itself.

For some of the galaxies in Table 1 it would not be difficult to measure detailed 21-cm line profiles with narrow-band equipment, and then to determine redshifts with an accuracy higher than that available from optical measurements.

PHYSICS

Townsend's First Ionization Coefficient for Compressed Nitrogen

THERE is a growing interest in the use of compressed gases, especially nitrogen and sulphur hexafluoride, for high-voltage insulation. However, there have been few measurements of the fundamental parameters, such as the Townsend α -coefficient, in gases at pressures above atmospheric. Allen¹ has made measurements at pressures up to 4 atmospheres absolute in nitrogen and has shown that, for values of E/p (electric stress/pressure) greater than 40 (V/cm)/mm mercury, the value of α agrees well with results from work at pressures below atmospheric. In the work recorded here it has been possible to extend measurements in high-pressure nitrogen down to $E/p_0 = 31.5$ (V/cm)/mm mercury (p_0 is the pressure corrected to 0° C) with pressures up to 10 atmospheres.

The pre-breakdown current was measured as a function of electrode spacing d , and α was derived from the Townsend relation:

$$i = i_0 \exp \alpha d$$

The initial current i_0 was 6×10^{-13} amp and was induced from a nickel cathode by directing ultra-violet light through a perforated anode of stainless steel. The total current i was restricted to less than 2×10^{-10} amp and electrode spacings up to 5 mm were used. The electrode had a 2.5-cm diameter plane area with 1.3-cm radius edges. Before assembling the test cell the plane areas of the electrodes were polished on a felt disk impregnated with 1 μ diameter diamond dust and were then washed in *n*-hexane. The test cell was evacuated to a pressure of about 0.3 mm mercury for several hours before measurements were made. The nitrogen used was 99.9 per cent purity (British Oxygen Co., Ltd.).

The values of α/p_0 are shown in Fig. 1 and it can be seen that they agree remarkably well with previous values taken from work at low pressures²⁻⁴. The higher α values found by Heylen⁵ may be due to his use of a very high-purity gas sample (99.998 per cent). In this investigation the values for E/p_0 greater than 38.6 (V/cm)/mm mercury were derived from measurements at 2 atmospheres absolute, but work involving the examination of individual avalanche growth⁶ has shown that the same values are obtained at 7 atmospheres absolute. At the lowest value of E/p_0 , 31.5 (V/cm)/mm mercury, measurements were made at 6, 8 and 10 atmospheres absolute.

As might be expected, these results confirm that α/p_0 is a function of E/p_0 and independent of pressure. Measurements at different pressures and constant E/p_0 yielded results of α/p_0 which agreed to within 4 per cent. Both E and p_0 could usually be measured with an error of less than ± 1 per cent, although an error in pressure of ± 2 per cent may be possible at the lowest pressure of 2 atmospheres absolute.

Fig. 1. α/p_0 versus E/p_0 in nitrogen. —, Present work, ---, ref. 5; O, ref. 3; □, ref. 4, Δ, ref. 2.

In view of the need for a better understanding of the breakdown process in compressed gases, it would be useful to extend measurements of α to much lower values of E/p_0 . However, such measurements may prove difficult. At pressures above 10 atmospheres Paschen's law is no longer valid^{7,8} and current measurements are hampered by low and erratic electric strengths. For example⁹, with stainless-steel electrodes and a 1-mm gap in nitrogen at 26 atmospheres absolute, breakdown was found to occur at a stress of about 150 kV/cm, when $E/p_0 = 8.3$ (V/cm)/mm mercury. Also, care has to be taken at higher pressures because the high electrical stresses involved lead to field emission. At pressures above 10 atmospheres the electric strength as well as field emission becomes dependent on the nature of the electrode surfaces. Consequently, a careful choice of electrode material and method of electrode preparation will be necessary if Townsend's α coefficient is to be determined for E/p_0 less than 30 (V/cm)/mm mercury and p_0 greater than 7,600 mm

mercury. In this work it was found important to keep the electrode surfaces reasonably dust-free, and with a nickel cathode it was possible to reach a stress of 220 V/cm without appreciable field emission. Work in this laboratory on compressed methane⁶ has also shown that high electric strength and low field emission can be obtained with a heavily oxidized copper cathode.

CHEMISTRY

Phosphorus-31 Chemical Shifts in Secondary and Tertiary Phosphines

ALTHOUGH several theoretical and empirical attempts¹⁻⁴ have been made to predict the ³¹P chemical shifts of phosphorus compounds, these have seldom achieved an accuracy of better than 10–20 p.p.m. For example, Van Vazer *et al.*³ assigned to alkyl groups the 'group shift' of +20 p.p.m. in trivalent phosphorus compounds. On this basis a tertiary phosphine should have a ³¹P chemical shift of about +60 p.p.m. However, the known values for twenty tertiary phosphines (Table 1) vary widely from his prediction, ranging from –19.3 to +62 p.p.m.

Table 1. CALCULATED AND OBSERVED CHEMICAL SHIFTS OF TWENTY-NINE PHOSPHINES

* Our measurements.

Others⁴ have noted a regular variation in the chemical shift of a tertiary, secondary, or halo-phosphine on stepwise substitution of the alkyl groups by other alkyl groups.

In the course of studies with a variety of phosphines and their derivatives, we have found that the ³¹P chemical shift (Δ p.p.m., relative to 85 per cent phosphoric acid) of a tertiary phosphine is given by equation (1) with a standard deviation of 1.0 for twenty compounds

$$\Delta (\text{p.p.m.}) = 62 - \sum_{n=1}^3 \sigma_n^P \quad (1)$$

of which the shifts have been measured. Further, the ³¹P chemical shift of a secondary phosphine is given by equation (2) with a

$$\Delta (\text{p.p.m.}) = 99 - 1.5 \sum_{n=1}^2 \sigma_n^P \quad (2)$$

standard deviation of 2.3 for the nine compounds for which data are available. More accurate estimation of the chemical shift by use of fractional σ^P values was not attempted since the accuracy of experimental chemical shifts is only about ± 1 p.p.m.

Insufficient data on primary phosphines are available to give a similar generalization for them.

The values for the constant σ^P for several organic groups are given in column 2 of Table 2.

Table 2. COMPARISON OF σ^P CONSTANTS WITH TAFT AND HAMMETT CONSTANTS

R Group	σ^P	σ^*	σ_m	σ_p
Me	0	0.0	–0.07	–0.17
Et	+14	–0.10	–0.07	–0.15
<i>n</i> -Pr	+10	–0.115	–0.05	–0.13
<i>i</i> -Pr	+27	–0.19	–0.07	–0.15
<i>n</i> -Bu	+10	–0.13	–0.07	–0.16
<i>i</i> -Bu	+7	–0.125	–	–0.12
<i>cy</i> -Hx	+23	–0.15	–	–
Ph	+18	+0.60	+0.06	+0.01

Fig. 1 shows the observed chemical shifts of the tertiary and secondary phosphines plotted against $\sum \sigma^P$, and Fig. 2 shows the observed chemical shifts of all twenty-nine phosphines plotted against the values obtained from equations (1) and (2). The numerical values are listed in Table 1.

The basicities of primary, secondary, and tertiary phosphines have been shown by Henderson and Streuli⁹ (with the use of Taft¹⁰ σ^* constants) to display a similar additive substituent effect, but inspection of the σ^* constants for various groups given in column 3 of Table 2 reveals little correlation between them and the corresponding σ^* constants. The *meta* and *para* Hammett σ constants likewise fail to display correlation with σ^P .

Fig. 1. Observed chemical shifts in relation to $\sum \sigma^P$. Δ , Secondary phosphines; \bullet , tertiary phosphines

Fig. 2. Observed chemical shifts in relation to chemical shifts calculated from equations (1) and (2). Δ , Secondary phosphines; \bullet , tertiary phosphines

The σ^* constants are essentially measures of inductive effect and thus it follows that the inductive effect is not the only factor influencing the ^{31}P chemical shift. Indeed, the order of the σ^* constants indicates that the inductive effect is not the major factor in determining ^{31}P chemical shift. Resonance effects, such as hyperconjugation involving the phosphorus $3d$ orbitals¹¹, may contribute and, in addition, steric effects which alter the bond angles and thus the hybridization of phosphorus are important². The resulting different anisotropies about phosphorus would markedly affect the chemical shift, but sufficient data are not yet available to determine the relative magnitudes of the different effects.

Work is continuing on derivatives of these and other phosphines with the aim of establishing similar relationships.

This work was supported in part by a National Science Foundation grant G-24443. The Advanced Research Projects Agency, Department of Defence, purchased the phosphorus nuclear magnetic resonance equipment. Both of us are recipients of the University of Maryland General Research Board awards, 1964.

Relative Ionization Efficiencies of Hydrocarbon Molecules as a Function of Bombarding Electron Energy

It has recently been shown that ions play an important part in the radiation chemistry of alkanes¹. Since the ionizations that occur during γ - or fast electron-radiolyses are caused by interactions of molecules with electrons of a wide range of energies, it is desirable to obtain information about the relative ionization efficiencies of different types

of hydrocarbons as a function of bombarding electron energy.

Recent results of Schram *et al.*² can be used to show that the relative ionization cross-sections (RICS) of saturated and unsaturated hydrocarbons are constant over the electron energy-range of 12,000 eV–600 eV and are approximately (within ± 15 per cent from methanol to benzene) proportional to the total number of electrons in the molecule. Results of Kebabian and Godbole³ can be used to show that the RICS of hydrocarbons are constant within an experimental uncertainty of about 20 per cent over the electron energy-range of 5,000 eV–70 eV. The work recorded here extends these investigations from 70 eV to 15 eV.

Cross-sections for the ionization of molecules by 75 eV electrons are proportional to the polarizabilities of the molecules⁴. For a given type of molecule, the cross-sections for 75 eV electrons are also proportional to the number of valence electrons in the molecules⁵. The excitation potential of the K -shell electrons in a carbon atom is 280 eV (ref. 6) so these electrons would not be affected by bombardment with 75 eV electrons.

In this communication the RICS of a compound will be expressed as the ionization cross-section (ICS) per valence electron in the compound relative to that per valence electron in *n*-butane:

$$\text{RICS of molecule} = \frac{\text{ICS of molecule}/\text{No. of valence electrons in molecule}}{\text{ICS of } n\text{-butane}/26}$$

Butane was chosen as a standard for comparison because it is common to the investigations of Schram² and Kebabian³.

The RICS of cyclohexane, cyclohexene and benzene are shown in Fig. 1 as a function of bombarding electron energy. The results were obtained with the aid of an Associated Electrical Industries, Ltd., MS2H mass spectrometer. The values of RICS are unity, within experimental error, for all the compounds down to bombarding electron energy of 20 eV. The ionization potentials of these compounds are: butane, 10.8 eV; cyclohexane, 10.3 eV; cyclohexene, 9.2 eV; benzene 9.2 eV (ref. 7). The absolute ICS of a molecule decrease rapidly as the energy of the bombarding electron approaches the ionization potential of the molecule^{7,8}. The absolute ICS of *n*-butane decreases more rapidly than those of cyclohexane, cyclohexene and benzene at energies below 20 eV, so the RICS of the latter compound increase.

The values of RICS are constant down to an electron bombarding energy that is only double the ionization potential of the molecules.

Fig. 1. Relative ionization cross-sections (RICS) of benzene, cyclohexene, and cyclohexane as a function of bombarding electron energy. The RICS values were determined relative to the ionization cross-sections of *n*-butane at the respective electron energies

The ICS of a hydrocarbon is proportional to the total number of electrons in its molecule for electron bombarding energies above 600 eV (ref. 2) and is proportional to the number of valence electrons in its molecule for bombarding electron energies between about 300 eV (the ionization potential of a *K* electron in carbon) and 20 eV. In mixtures of hydrocarbons, 'valence electron' fractions do not differ by more than 10 per cent from the 'total electron' fractions. In view of the wide energy spectrum of the electrons that cause ionization during the radiolysis of a system, the assumption that the initial distribution of ionizations among the components of a mixture of hydrocarbons is according to the respective 'total electron' fractions of the components is adequate. Furthermore, the fact that total electron fractions emphasize unsaturated compounds slightly more than do valence electron fractions tends to compensate for the fact that the RICS of unsaturated compounds is greater than that of saturated compounds at low bombarding energies.

Fig. 2. Fragmentation patterns of *n*-butane, benzene, cyclohexane, and cyclohexene as a function of bombarding electron energy. The ion currents due to the individual ions are expressed as fractions of the total ion current. Only the major ions are represented.

An additional piece of information is available from the present work. Kebarle and Godbole³ determined that the relative abundances of the major ions in the mass spectrum of a hydrocarbon were nearly constant over the bombarding electron energy-range of 10,000 eV–70 eV. The present results project this investigation to lower energies. The relative abundances of the major ions in the cyclohexane, cyclohexene, benzene and *n*-butane mass spectra are shown in Fig. 2 for bombarding electron energies in the range of 70 eV–12 eV. The relative abundances of the major ions from all the compounds are essentially independent of electron energies down to 40 eV. This means that, neglecting minor processes such as inner-shell excitation, the energy distribution of excited hydrocarbon ions is independent of bombarding electron energy above about 40 eV (about four times the binding energy of the electrons being perturbed).

Androgenic Steroid Complexes with *p*-Bromophenol

ONE of the major problems encountered in using the heavy atom X-ray method¹ to determine the structure of steroids^{2,3} (or any other molecule) is the possibility that the direct attachment of a heavy atom to the molecule will cause distortion. Theoretically, the amount of distortion is determined by steric factors and the stability of the electronic configurations adjacent to the site of attachment. For example, when a bromine atom is covalently attached to carbon four of an aromatic A-ring of the steroid nucleus, it is reasonable to expect that the resulting distortion would be insignificant, because of the stability imparted to the A-ring by the aromatic system. Experimental evidence supporting this expectation was obtained in the molecular-structure determinations of 4-bromoestrone² and 4-bromoestradiol³. In these brominated steroids, the A-rings are extremely planar (non-planarity coefficients 0.02 Å in both cases) despite the covalently attached bromine.

On the other hand, when a heavy atom is attached to non-aromatic rings (or to various side groups) which lack the stability of the electronically imposed planarity of aromatic rings, considerable distortion should be expected, especially in the immediate vicinity of the molecular perturbations caused by the substitution. Evidence supporting this is suggested by the fact that the absorption spectra of some of the nuclear-substituted bromo-derivatives of steroids (such as the α -bromo ketones) are distinctly different from the absorption spectra of the unbrominated compounds. This is so because the equatorial halogen, which is co-planar with the carbonyl group, interacts inductively with the carbonyl group, shortening and strengthening the C=O double bond. This results in a small hypsochromic shift in the ultra-violet and in a larger change in the infra-red region where the frequency of the carbonyl stretching mode is increased as much as 20 cm⁻¹. Axially attached bromine, on the other hand, produces a pronounced bathochromic shift in the ultra-violet of about 20–30 m μ but no changes in the infra-red. In extreme cases, such as the 6 β (a)-bromo- Δ^4 -3-oxosteroids, the compounds are quite labile and can be de-hydrobrominated with comparatively mild reagents⁴.

Papers reporting the amount of distortion in quantitative terms are scarce in the literature. We have been unable to find examples of X-ray structure determinations of compounds approximately the same size as steroids with and without a heavy atom. It is hoped that when the work has been completed, the structure determinations of 16- and 21-bromo isomers of 5 α -pregnan-3 β ,17 α -diol-11,20-dione, at present being made in our laboratory, will shed some light on the problem. In the meantime, we have turned our attention to another approach.

The whole idea of the heavy atom method is to add a few heavy atoms to the unit cell which are crystallographically arranged and which have high enough atomic scattering factors to dominate the phases of the waves scattered by the total contents of the unit cell. Thus, from the point of view of crystal structure determination, it is completely unimportant whether or not the heavy atoms are bound to the molecule the structure of which is being determined. The whole problem of molecular distortion by the covalent binding of heavy atoms may be circumvented by the co-crystallization of the steroid molecule with a smaller molecule containing an appropriate heavy atom. With this idea in mind, one of us (C. E.) undertook to prepare such complexes. The purpose of this communication is to report the preparation, heavy atom analysis, spectroscopic data, and single crystal X-ray diffraction

data for a series of molecular complexes between some of the androgenic steroids and *p*-bromophenol.

The steroids and the *p*-bromophenol were mixed in a 1:1 molar ratio, dissolved in *n*-hexane, and left in stoppered vials for crystallization. In an effort to obtain crystals suitable for X-ray analysis (diameter ≈ 0.03 mm), the vials were kept in vacuum flasks heated by a thermoregulated electrical resistance coil and the temperature reduced gradually from 60°C to room temperature over a period of approximately one week. The mother liquor was decanted and the crystals washed thoroughly with *n*-hexane and afterwards dried at 40°C in a vacuum.

The products were subjected to combustion in a Schöniger oxygen flask⁵ and afterwards analysed for bromine by potentiometric titration of the bromide formed with a calibrated silver nitrate solution. The results of these analyses are given in Table 1.

Infra-red absorption spectroscopy is one of the powerful tools for the detection and quantitative evaluation of the hydrogen bond. It has been well established in a surprisingly large number of papers that molecular association between phenols and ketones is stabilized by hydrogen bonding, the phenol acting as a proton donor and the carbonyl group as the acceptor⁶⁻¹³. In general, the inter-

molecular association involving hydrogen bonding is characterized by a number of changes in the specific absorption bands of the participating functional groups.

The OH stretching mode of the alcohol or phenol is shifted to lower frequencies because of the increase of the O—H bond length. A similar decrease in frequency is observed for the C=O stretching mode of a carbonyl group participating in hydrogen bonding as a proton acceptor, while the C—O—H deformation mode (that is the in-plane bending of the alcoholic or phenolic O—H) is shifted to higher frequencies. In all these cases the amount of shift and absorptivity is related to the strength of the hydrogen bond involved¹⁴.

Our preliminary infra-red spectroscopic measurement support the assumption that intermolecular complexes between androgenic steroids and *p*-bromophenol are hydrogen bonded (Table 2). This is indicated by a shift of the C=O stretching of the steroid carbonyl groups to lower frequencies: 1,744–1,728 cm⁻¹ for androsterone and 1,680–1,658 cm⁻¹ for testosterone. A similar change of the OH stretching can be observed for the phenolic OH group. Thus, when steroid is added to the *p*-bromophenol solution, the intensity of the monomeric OH band at 3,610 cm⁻¹ is decreased, while a new broad band between 3,400 cm⁻¹ and 3,340 cm⁻¹ appears, due to the hydrogen bonded OH group. A self-association of the *p*-bromophenol can be detected at higher concentrations in the 3,400–3,520 cm⁻¹ range with a peak at 3,480 cm⁻¹. There is considerable overlap of the association bands in this region, presumably because of different hydrogen bonded molecular species formed by the *p*-bromophenol. Additional evidence of association by hydrogen binding is the frequency shift of the OH deformation modes of the *p*-bromophenol. Phenol and some of its substituted derivatives show two bands in the 1,180 cm⁻¹ and 1,330 cm⁻¹ regions, the first with a more pronounced OH character demonstrated by a larger hydrogen bond induced frequency shift. It has been concluded that at least one of these modes is the coupled vibration between the OH bending and the C—O stretching mode; the latter, coupled with the benzene ring vibration¹⁵, absorbs in the 1,250 cm⁻¹ region. Although definite assignments of these two bands are still questioned, it has been shown that both respond to hydrogen bond formation. In our measurements we observed a definite weakening of the 1,176, 1,168 cm⁻¹ 'doublet' of the *p*-bromophenol and the appearance of a new band at 1,215 cm⁻¹, which is a shift of approximately 40 cm⁻¹. On the other hand, we were unable to identify with certainty a corresponding shift in the 1,300 cm⁻¹ region. Results similar to those described here were obtained with cyclohexanone and cyclopentanone, the ketonic ring system found in the steroids, and they are included here for comparison. The C=O stretching band of cyclohexanone is shifted from 1,718 cm⁻¹ to 1,703 cm⁻¹, and the one for cyclopentanone from 1,749 cm⁻¹ to 1,728 cm⁻¹, while the OH stretching and the deformation modes of the *p*-bromophenol show the changes already mentioned.

At the present time, we do not have enough evidence to identify the interaction between the bromine and the teroidal alcohol group which is suggested in the two cases in which the molar ratios of steroid and bromophenol are 3:2 and 2:1 respectively. From our data, however, it is evident that the intensity of the alcoholic absorption bands (3,628 and 3,635 cm^{-1}) decreases with the concentration increase of *p*-bromophenol, indicating intermolecular hydrogen bonding.

Unit cell constants were measured on a General Electric XRD-5 X-ray diffraction unit equipped with a single crystal orienter, using copper $K\alpha$ radiation. Space groups were determined from considerations of Friedel symmetry and optical activity. Densities were determined by flotation. All the crystals examined appear to be good enough to be used in structure determinations, although some of them may have to be mounted in sealed glass capillary tubes to protect them from atmospheric moisture or possible loss of volatile components. The single crystal data are given in Table 3.

In addition to offering a useful tool in the X-ray crystallographic determination of steroids, the molecular complexes between androgenic steroids and *p*-bromophenol described in this communication are of considerable biological interest. Since phenol groups are often present in proteins, perhaps the type (or types) of binding responsible for the formation of the complexes reported here are also important in steroid-protein interactions. It is interesting to note that similar complexes between other androgenic steroids (also progestational steroids) and β -naphthol, resorcinol, phloroglucinol, and naphthalene have been reported in the recent literature¹⁶.

We thank Chia Tang Lu for obtaining the single crystal data and Carl Reggie for helping with some of the chemical procedures. This investigation was supported in part by U.S. Public Health Service research grant (CA-06183) from the National Cancer Institute and in part by research grant (UHF-G-64-RP-7) from the United Health Foundation of Western New York.

salts in moist organic solvents with amines of high molecular weight⁴. We wish to report further details of the various solid forms of ampicillin, both anhydrous and hydrated, and the means whereby they may be inter-converted.

Ampicillin is normally isolated from aqueous solution by adjusting the pH to 4-6.5, followed, if necessary, by concentration at low temperature and pressure, whereupon, provided the solution is reasonably pure, needle-like crystals separate readily⁵. However, if much impurity is present, which may happen with some preparative methods, the initial product may consist of heavily hydrated agglomerates, although slurring with water to which sufficient alkali has been added to bring the pH to between 7 and 8 readily converts such solid into the crystalline form⁶. The first crystals obtained in this laboratory were dried *in vacuo* over phosphorus pentoxide prior to analysis, and then had the elemental composition of a monohydrate⁵. However, when the crystals from subsequent runs were dried in air at temperatures up to about 65° C they proved to be the trihydrate. Further drying *in vacuo*, even at room temperature, readily reduced the water content to the monohydrate level, but dehydration beyond this stage was slow.

Grant and Alburn² heated an aqueous suspension or slurry of the monohydrate at 40°-100° C for a few minutes to give crystalline anhydrous ampicillin. In this laboratory the anhydrate was similarly prepared from any form of ampicillin⁷, although reasonably rapid conversion of trihydrate required a temperature of 80°-100° C. Hydrated ampicillin was also converted into the anhydrate by heating a suspension in nitromethane or other nitrohydrocarbon⁸.

The various forms of ampicillin may be distinguished by their infra-red spectra in the solid state (Fig. 1). The broad-banded spectrum attributed by Grant and Alburn²

Fig. 1. Infra-red spectra of ampicillin forms (0.4 per cent in potassium bromide). (1) Trihydrate; (2) anhydrate; (3) other forms

Crystalline Modifications of Ampicillin

SINCE the introduction in 1961 of 6[D(-) α -amino-phenyl-acetamido]penicillanic acid¹ (I; ampicillin), its synthesis, bacteriology, pharmacology, and clinical use as a broad-spectrum penicillin have been extensively reported. Recently, attention has been turned to the physical properties of the solid. Thus, Grant and Alburn² have distinguished between a crystalline anhydrous form and a monohydrate, which differ in solid-state infra-red absorption spectra, density, solubility, and thermal stability. They make no mention, however, of the highly crystalline ampicillin trihydrate which may be obtained by crystallization from water³ or by treating acid addition

to the monohydrate is, in our experience, typical of trihydrate which has been kept *in vacuo* to reduce the water content to any level below about 10 per cent, and also of amorphous or freeze-dried specimens containing up to about 20 per cent water. This type of spectrum (No. 3) may be contrasted with those of the anhydrate and trihydrate, in both of which the bands are sharp and well resolved. Spectra of the trihydrate (No. 1) and anhydrate (No. 2) differ chiefly in the NH and OH stretching region, where a sharp isolated band at 3.00μ is characteristic of the anhydrate, and in a group of bands between 6.05 and 6.7μ which include the carbonyl stretching band of the ionized carboxyl group, the 'amide II' (NH/CN combination) band, and possibly an NH_3^+ deformation band. In the latter region the trihydrate shows a shoulder at 6.14μ and bands at 6.21 , 6.34 and 6.66μ , whereas the anhydrate shows distinct bands at 6.08 and 6.32μ as well as a compound band centred at about 6.6μ . An unassigned medium-intensity band at 7.48μ appears to be characteristic of the trihydrate.

Grant and Alburn² attribute the diffuseness of their monohydrate spectrum to a low degree of order in the crystal; by the same token the trihydrate and anhydrate crystals should both be highly ordered. The spectrum of the trihydrate suggests that the three water molecules may be intimately associated with the two ionized groups and with the amide NH group. With all the water molecules thus rigidly bound, the trihydrate is as stable as the anhydrate to normal storage, while its lower stability above 70°C is probably due to break-down of the crystal lattice and rupture of the sensitive β -lactam by the liberated water. When part of the crystal water is removed *in vacuo* stability is decreased, possibly due to greater freedom of movement in the impaired lattice.

The solubility of the crystalline anhydrate in water is relatively little affected by temperature, being approximately 1.1 per cent at 30°C and 1.3 per cent at 87°C , whereas that of the trihydrate is only 0.7 per cent at 30°C but increases fairly sharply with temperature so that the two solubility curves intersect at about 50°C . Solutions of ampicillin in one equivalent of N hydrochloric acid were stirred at various temperatures while the calculated quantity of 2 N sodium hydroxide was added and crystallization occurred. Crystals separating below 50°C proved to be pure trihydrate, above 60°C they were the anhydrate, while at intermediate temperatures the solid was shown spectroscopically to contain both forms. The trihydrate and anhydrate, each in their appropriate temperature ranges, thus appear to be the only crystalline forms capable of existing in equilibrium with the saturated solution. We therefore believe that samples of ampicillin which have been recorded as the monohydrate^{2,5,9}, dihydrate⁴ or sesquihydrate¹⁰ were either amorphous or consisted of partially dehydrated trihydrate.

We thank Mr. A. E. Bird, Dr. H. D. C. Rapson and Dr. J. H. C. Naylor for their advice.

BIOCHEMISTRY

Photochemical Synthesis of Condensed Phosphates

In the course of unsuccessful attempts to use *metanitrophenylphosphate* as a photochemical phosphorylating agent¹, we noted the appearance of pyrophosphate in a number of our control tubes. Further experiments have shown that ultra-violet irradiation of solutions of phosphoric acid or *tetrabutylammonium dihydrogen phosphate* in certain pyridine derivatives or in aliphatic ketone leads to the formation of condensed phosphates. In this communication we describe our semi-quantitative observations on these systems. We examined 0.01–0.05 M solutions of phosphate in the following solvents: pyridine 2-, 3-, and 4-picoline, acetone, methyl ethyl ketone, pyruvic acid, acetylacetone, benzaldehyde, acetophenone, anisole, *n*-butyraldehyde and propionaldehyde. Only those listed in Table 1 were we able to detect pyrophosphate. (The sensitivity of our method was ≈ 0.5 per cent conversion.) Irradiations were carried out in a RPR-10 'Rayonet' photochemical chamber using RPR-2537 lamps for the ketone solution and RPR-3500 Å lamps for the pyridine solutions. The solutions were contained in quartz tubes 10 mm in diameter. The temperature of the solutions was $45^\circ \pm 5^\circ\text{C}$.

Table 1. PERCENTAGE CONVERSION OF ORTHOPHOSPHATE TO PYROPHOSPHATE IN ULTRA-VIOLET-IRRADIATED SOLUTIONS. THE RESULTS ARE EXPRESSED IN PERCENTAGE OF PHOSPHORUS PRESENT IN PYROPHOSPHATE

Solvent	Solute	Conc. (M)	Time of irradiation (h)				
			16	32	48	80	170
Pyridine	(Bu ₄ N)H ₂ PO ₄	0.05	2	5–7		15	15
	H ₃ PO ₄	0.05	2.5	2.5		2.5	
2-Picoline	(Bu ₄ N)H ₂ PO ₄	0.05	1.5	5		5	
3-Picoline	(Bu ₄ N)H ₂ PO ₄	0.05	1.5	5		10	8–10
4-Picoline	(Bu ₄ N)H ₂ PO ₄	0.05		1		3	5–8
Acetone	(Bu ₄ N)H ₂ PO ₄	0.025	7				
	H ₃ PO ₄	0.05	8	8	8		
Methyl ethyl ketone	(Bu ₄ N)H ₂ PO ₄	0.01	20				
	H ₃ PO ₄	0.05	7				

Rough quantitative estimates of the extent of conversion of phosphate to pyrophosphate under a variety of conditions are given in Table 1 (ref. 2). The consequences of prolonged irradiation are more complex and less reproducible, probably because the organic solvents undergo extensive degradation. However, two phenomena of considerable interest were observed repeatedly; namely the formation of tripolyphosphate in solution and the formation of precipitates containing much of the phosphorus as pyrophosphate, tripolyphosphate, and trimetaphosphate.

We first became interested in these novel reactions in the context of 'origins of life' investigations. However we now doubt that our findings have any relevance. While the reaction proceeds equally well in damp pyridine and in pyridine dried over calcium hydride, the addition of 50 per cent water completely quenches the condensation. Until a condensing agent can be found which brings about pyrophosphate formation in aqueous solution, the involvement of reactions of this type in prebiological synthesis remains without experimental support. Our experimental findings do not permit any conclusions concerning the mechanism of the reactions.

We understand that Dr. C. Zioudrou and Prof. G. Stein have made related observations.

Effect of Hydrolysed Glucose Cycloacetoacetate in the Prevention of Fatty Infiltration in the Liver

GLUCOSE cycloacetoacetate (GCA) while hydrolysed with dilute hydrochloric acid has been found to have beneficial effects in experimental diabetes¹⁻³. It has also recently been observed in this laboratory to facilitate transmethylation reactions in *E. coli*⁴. It was reported earlier by Saikia, Brahmanekar and Nath⁵ that hydrolysed glucose cycloacetoacetate in a daily dose of 80 mg/100 g body-wt can cause considerable desaturation of the liver fat, which, according to Schoenheimer and Rittenberg⁶, is an indication of increased fat metabolism. Nath and Saikia^{7,8} have also observed earlier the prevention of atherosclerotic and hyperlipaemic conditions in animals by the hydrolysed product of glucose cycloacetoacetate (GCAH). Investigations were therefore undertaken to observe the lipotropic effect of GCAH in experimental animals. Because vitamin B₁₂ is known to have a lipotropic effect it was also thought desirable to study the effect of very small doses of vitamin B₁₂ in partially hepatectomized animals.

Table 1

No. of animals	Treatment Substance	Period	Fat in liver just after partial hepatectomy (per cent)	Fat 48 h after partial hepatectomy (per cent)	Increase of fat (per cent)
6	Nil	—	5.18 ± 0.25	8.95 ± 0.32	72
6	GCAH inject	From 3 days before partial hepatectomy	5.08 ± 0.15	5.31 ± 0.14	2.5
4	20 mg/kg GCAH inject	"	4.86 ± 0.14	4.90 ± 0.12	0.8
6	25 mg/kg Vlt. B ₁₂ inject	"	5.10 ± 0.11	5.96 ± 0.15	16.8
	10 µg/kg				

Montini and Pontremoli⁹ have reported that, 48 h after partial hepatectomy of the rat, the remaining portion of the liver undergoes fatty degeneration with a very large increase in the percentage of fat. This technique was used in this investigation and the experiment was made with twenty-two rats each weighing about 200 g. Sixteen animals were used for the experiment and six as control. GCAH and vitamin B₁₂ were injected intraperitoneally for three consecutive days before partial hepatectomy and for 2 days more thereafter before killing. The results are shown in Table 1.

It is thus evident from the results that GCAH, which has been found to help formation of methionine¹⁰ as well as choline¹¹ in liver, is also lipotropic in nature.

Further investigations are in progress.

Rapid Method for Selenium Assay of Plant Material

WE have found the following to be a particularly rapid and reproducible means of assaying for selenium in leafy plant material. It is based on the use of perchloric acid and H₂O₂ to facilitate digestion and clarification of the sample and on the spectrophotometric determination of

the elemental selenium produced on reduction of the combined forms of the element. Our method represents, in part, a combination of techniques recently found useful for higher plant and microbial material¹⁻³.

We used the selenium accumulator *Astragalus bisulcatus* L. in soil watered once daily with 1 p.p.m. of selenium as Na₂SeO₃·5H₂O and the closely related non-accumulators *A. canadensis* L. and *A. succulentus* L., grown in the same way except that no selenium was added to the soil in which the latter species were grown.

Approximately 0.5 g fresh weight of the plant sample containing Se is placed in a 250-ml. Erlenmeyer flask, to which is added 10 ml. of the digesting mixture consisting of 3 parts conc. HNO₃ and 1 part of HClO₄ (60 per cent). The mixture is heated gently on a hotplate until all the HNO₃ is driven off and the fumes of HClO₄ begin to fill the flask. After the material is completely digested, the flask is cooled thoroughly in cold water. 2–3 ml. H₂O₂ is added, and after 5 min or more the flask is reheated until fumes of HClO₄ appear again, and all the H₂O₂ has been expelled. The clear and colourless sample is again cooled and the flask is then placed into a boiling-water bath for 2–3 min. A mixture of 10 ml. of a 3 per cent hydrazine sulphate solution plus 3 ml. of a 2.5 per cent solution of gum arabic is added. It is extremely important to add the mixture in aliquots of 2 ml. or less and to allow a short period of time between addition. The flask is then placed in the boiling-water bath for 10 min, by which time the characteristic orange-red colour of elemental Se should be fully developed. The suspension is transferred to a volumetric flask and made up to 25 ml. with distilled water. The absorbancy of the samples at 420µ is measured in a spectrophotometer (Beckman DU) and the Se concentration is calculated using the straight-line calibration curve obtained from known concentrations of elemental Se. To prepare the standards, 1.0 g elemental Se is added to 10 ml. concentrated HNO₃ and the mixture heated to dryness on a hotplate. 10 ml. distilled water is added, and the suspension is again dried by heating. The addition of water and heating is repeated twice. The Se is now treated as in the preparation of the unknown sample, except that the H₂O₂ can be omitted, as has been shown by preliminary tests. The final dilutions can be varied according to the expected range of Se concentrations in the unknown samples. The Se concentration of *A. bisulcatus* L. averaged 1,100 p.p.m., while the non-accumulators averaged 0.03 p.p.m., all on a fresh-weight basis.

This work was supported by U.S. Public Health Service grant A100596-C. We thank L. Sonsteli for technical assistance, and Dr. O. A. Beath of the University of Wyoming for seed of the *Astragalus* species.

Disruption of Protozoa by Indole and Related Compounds

THE disruption of protozoa in saturated aqueous indole solutions, first described by Eadie and Oxford¹, has been used in the preparation of enzyme extracts from rumen protozoa² and ribosomes from *Tetrahymena*³. This type of biochemical disruption is of interest not only because of its spectacular nature but also because it is selective for rumen protozoa and any associated bacteria are not broken². In examining the disruptive effect of other compounds Eadie and Oxford¹ confined themselves largely to those closely related to indole and skatole (see Table 1). They concluded that, while a fairly close relationship to the tryptophan structure might be important, the

Table 1. DISRUPTION OF PROTOZOA BY SOME ORGANIC COMPOUNDS

	<i>Tetrahymena</i>		<i>Rumen protozoa</i>	
	Killed	Disrupted	Killed	Disrupted
(a) Present work

Aniline, tryptamine, tryptophan, indolyl-3-acetate, -propionate, -butyrate	-	-	-	-

- = non-toxic or not disrupted.

primary requisites for disruption were "slight water solubility with ready lipid solubility and the absence of any strongly polar centre in the molecule". We have now examined the disruptive action of a much wider range of compounds on both rumen protozoa and *Tetrahymena* in order to test these conclusions.

Mixed rumen protozoa were freshly isolated⁴ from the rumen contents of cattle fasted overnight; *Tetrahymena* were grown for seven days³. In each case the protozoa were collected by centrifuging (200*g*) and portions (0.1 g wet weight) suspended in 2 ml. solution (water at 20° C for *Tetrahymena*, buffer⁴ at 37° C for rumen protozoa) containing water-insoluble compounds at saturation and water-soluble compounds at 0.1 per cent w/v (equivalent to the indole concentration at saturation). The organisms were examined microscopically at intervals during 1 h and the following effects were distinguished: (a) no apparent effect, (b) loss of motility without disruption (killed only) and (c) loss of motility followed by complete disruption. In earlier work², rumen protozoa which had been isolated and incubated for 24 h were used and disruption with indole was slow; in contrast to this, *Tetrahymena* always burst instantly on contact with indole. The freshly isolated rumen protozoa used in the present work were more active organisms and when disruption occurred after addition to the test solution it was almost always instantaneous. The results obtained with various substances are summarized in Table 1.

These results show that protozoal disruption is not solely associated with indole and its derivatives but that the other conclusions of Eadie and Oxford¹ concerning

solubility and the absence of polar groups are substantiated. Thus, in general, all the disruptive compounds are only slightly soluble in water but show ready lipid solubility and have no strongly polar centre in the molecule. The strongly basic and/or water-soluble, single-ring heterocyclic compounds are largely non-disruptive under the conditions used, but the two-ring heterocyclic compounds are very active, because the presence of the fused benzenic ring increases the lipid solubility and decreases the basicity (except for tetrahydro-isoquinoline). Not all the lipid soluble compounds tested, however, are active. While in some cases this may be related to the fact that they are too insoluble in water (for example, naphthalene, carbazole, *n*-hexane), in other cases it could be due to the presence of a polar centre in the molecule (for example, aniline, ether). Our results suggest that solutions saturated with benzene rather than indole may be more convenient for disrupting protozoa. Control experiments have shown that the benzene in such extracts does not interfere with carboxylase activity and it has the advantage of not giving a false colour with the Folin-Ciocalteu proteolytic reagent as does indole².

PHYSIOLOGY

Cerebello-rubral Connexions in the Cat

SMALL stereotaxic lesions have been made unilaterally in each of the three cerebellar nuclei in a series of cats. After a survival period of 8-15 days, the animals were killed by intracarotid perfusion of 10 per cent formalin under anaesthesia. In each case, the cerebellum was cut in serial frozen section at 100μ and stained by the Nissl method. Projection drawings from these sections made it possible to localize and reconstruct the lesion.

Fig. 1. The upper row shows representative lesions in each of the three cerebellar nuclei. Below each diagram is a photomicrograph ($\times 310$) of the appearance of the contralateral red nucleus, impregnated by the method of Nauta, in the case of the lesion illustrated. Lesions of the fastigial (a) and lateral (c) nuclei produce no degeneration in the red nucleus, while a lesion of the n. interpositus (b) provokes intense pre-terminal degeneration.

The rest of the brain, apart from the cerebellum, was cut in serial frozen section at 30 μ , and every tenth section was impregnated by Nauta's modification¹ of the Nauta-Gygax technique². Examination of these sections for degenerating axons and pre-terminals enabled us to establish that no fibres from either n. fastigii or n. lateralis terminate in the magnocellular red nucleus (Fig. 1, a and c), though there is a small amount of pre-terminal degeneration in the pre-rubral region of the zona incerta following lesions of n. lateralis. In contrast to this, lesions of n. interpositus cause massive pre-terminal degeneration in the contralateral red nucleus (Fig. 1b). So far as the fastigial nucleus is concerned, these findings are in agreement with those of previous authors^{3,4}; but we cannot agree with Cohen *et al.*⁴ that there is any projection from the lateral cerebellar (dentate) nucleus to the red nucleus. The discrepancy may be due to the fact that we have been able to produce small coagulations which were confined to single cerebellar nuclei. It is interesting that only the nucleus interpositus appears to receive reciprocal afferent innervation from the red nucleus in the cat⁵.

Like Cohen *et al.*⁴, in the cat, and in contradistinction to the findings of Carrea and Mettler⁶ in the monkey and the electrophysiological study of Orioli⁷ in the cat, we were unable to find any evidence suggesting that fibres of the descending limb of the brachium conjunctivum extend below the level of the superior olive.

Delayed Mortality in Adult Chickens exposed to 1 Atmosphere Oxygen

THE growing chick (2-7-week-old White Leghorn) is markedly resistant to the usually lethal effects of 100 per cent oxygen at one atmosphere (OAP), exhibiting only a depressed growth rate and feed intake¹. It has been theorized that the different anatomy of the avian respiratory system might enhance resistance to a toxic agent believed to act primarily on the lungs. However, the young of several mammalian species are more resistant to the toxic action of OAP than the adults². The question of whether the chicks' mild reaction to OAP was a function of its young age or unique anatomy could not be decided from the literature, which, so far as the domestic fowl is concerned, appears to be limited to a report on three adults³. Therefore, further tests involving the exposures of mature White Leghorns to OAP were undertaken.

Continuous exposure to OAP took place in sealed plastic isolators similar to those used with chicks¹, except for the substitution of cages capable of holding one to two adult birds. Isolator conditions were controlled and physiological variables determined essentially as for the chicks, with the addition that body temperature (T_B) was measured by a rectal thermistor inserted 4-6 cm via the cloaca. Isolator conditions averaged: oxygen = 98 ± 2 per cent; carbon dioxide = less than 0.5 per cent; $T =$ between 23° and 28° C; relative humidity = mostly 100 per cent, except 42-65 per cent in two early trials. The birds used were single-comb White Leghorns ranging in age from 8 months (six males and three females) to

2 years (the remaining 10 females). About midway through the tests, adult white mice were introduced into the isolators to serve as biological indicators of the toxicity of the atmosphere.

Initial examination of mortality data showed no difference between 8-month-old and 2-year-old birds, hence survival time is presented in Table 1 without regard to age. The overall average survival time was 10 days, with no statistically significant difference due to sex. The range was 5-16 days, with one male still alive, but barely so, on day 16. These results are in general agreement with Soulie's⁴ results on three chickens, two of which survived beyond 11 days. By contrast, adult white mice exposed simultaneously to the same atmosphere lived only half as long, 5 days on the average, with a range of 4-8 days (Table 1).

A uniform observation in all trials was a complete cessation of both feed and water intake within 2 days, generally after 24 h, which was associated with a progressive lethargy. Because of the adipsia the relative humidity in the isolator was permitted to rise to saturation, for, although high humidity is reported to shorten survival in OAP⁴, we thought that dehydration in these extended exposures might be even more detrimental. The effect of the anorexia is seen in the 31-33 per cent loss in body-weight at time of death (Table 1).

Although feed intake ceased early, a dark, watery faecal material continued to be deposited throughout the stay in OAP. Post-mortem examination of the digestive system showed that in every case the tract from gizzard to cloaca was empty and free of overt lesions; however, in a number of animals the upper tract-crop, proventriculus and gizzard contained feed material in various stages of decomposition. It would seem that OAP inhibited motility anterior of the gizzard but not posteriorly, and the dark faecal deposits may have been desquamated intestinal debris mixed with bile segments.

Though primary interest in this work centred on survival time, a number of ancillary measurements were made at random during the course of the exposures (Table 1). The finding of a pO_2 of more than 400 mm mercury after an average of 8 days in OAP indicates that there was no barrier preventing contact between blood and the hyperoxic atmosphere. It suggests further that if hypoxaemia develops in these birds it must be quite late in the exposure. This was visually confirmed by maintenance of red colour in comb and wattles until near death. The haematocrit of 40 is high for adult hens⁵, probably reflecting dehydration resulting from the adipsia. Body temperature remained normal over most of the exposure, making it unlikely that the prolonged survival is due to any drastic depression in metabolism. In one or two birds a possible neural symptom was observed in the form of a twisting of head and neck as terminal events approached.

A marked effect of OAP was noted on respiration. Breathing rate decreased progressively with exposure finally degenerating into short gasps alternating with long periods of apnoea. Nevertheless, on post-mortem, lungs and thorax appeared for the most part grossly normal—certainly showing nothing comparable to the congestion, hyperaemia and oedema observed in the mice which died in OAP.

Table 1. EFFECT OF 100 PER CENT OXYGEN AT 1 ATMOSPHERE ON THE ADULT WHITE LEGHORN

		Male	Female
		(No.) av. \pm S.E.	(No.) av. \pm S.E.
Survival-time (days)	Chicken	(6) 9.5 \pm 1.5	(13) 10.7 \pm 0.8
		(19) 10.3 \pm 0.7	
Body-weight (kg)	Mice	(8) 5.0 \pm 0.5	
	Initial	(4) 1.74 \pm 0.12	(8) 1.45 \pm 0.23
	Final	(4) 1.17 \pm 0.04	(8) 1.00 \pm 0.16
	Per cent loss	31.2	32.7
Arterial O_2 tension (mm Hg) (av. exposure—8 days)			(4) 432 \pm 41
Venous O_2 tension (mm Hg) (av. exposure—8 days)			(3) 54 \pm 15
Haematocrit (per cent) (av. exposure—8 days)			(3) 40.0 \pm 3.8
Body temperature ($^{\circ}$ C) (av. exposure—7 days)			(4) 41.0 \pm 0.05
Respiratory rate (min) (av. exposure—10 days)			(4) 9.2 \pm 1.2

This investigation did not supply an unequivocal answer to our original question of whether the resistance of the growing chick to OAP was a function of its youth or of the different anatomy of the avian respiratory system⁵. The average survival time of 10 days for the adult is a far cry from the absence of mortality and morbidity after 4 weeks in the chick¹, and indicates that there must indeed be greater resistance with decrease in age in the chicken, as in the rat and possibly other species².

On the other hand, despite some similar reactions to OAP, for example, the anorexia and dyspnoea, there are definite differences in response between chickens and other species. Thus, simultaneously exposed mice survived on the average only half as long, 5 days, an interval which appears to be reasonably typical for most small- and medium-sized mammals, and perhaps even other birds^{2,3,6}, and, on post-mortem, the chicken shows little of the pulmonary congestion, hyperaemia and oedema typical of the mammal succumbing to OAP. It seems quite possible, in fact, that the extended period without eating or drinking could have contributed considerably to the death of the chickens.

There seems to be good reason to assume, therefore, that the chicken does have an inherently high resistance to OAP, and that it may be related to its specialized respiratory system. Pursuit of this problem could provide further understanding of the mechanism of oxygen toxicity—such as the role of atelectasis⁷, presumably less likely in the semi-rigid avian lung with its continuous air capillaries and air sacs, or the role of surfactant⁸, possibly deficient in the avian lung⁹.

Nerve Potential Recordings during electrically and mechanically evoked Monosynaptic Reflexes in Man

A MONOSYNAPTIC reflex can frequently be evoked in the calf muscles on electrical stimulation of the tibial nerve (*H*-reflex) at a stimulus intensity below threshold for the motor fibres. A centripetal nerve volley can sometimes be recorded below threshold for the α -motor fibres on stimulation of various peripheral nerves in the upper and lower extremity^{1,2}, in the distribution of which an *H*-reflex is an unusual occurrence. Yet Magladery *et al.*³, recording from the spinal roots with intrathecal electrodes, found, on stimulation of the tibial nerve, that an afferent volley did not occur until after the reflex volley had developed. One purpose of the work reported here was to investigate the relationship between centripetal nerve volleys and the threshold for the monosynaptic reflex in the calf muscles.

The *H*-reflex in the calf muscles has been identified as the electrically evoked counterpart of the ankle jerk^{4,5}. However, the tendon jerk depends additionally on the sensitivity of the muscle spindle organs the activity of which is controlled by fusimotor fibres. The identity of the mechanically and electrically evoked monosynaptic reflexes forms the basis of a system for analysing changes in fusimotor function⁶⁻¹⁰. Another aim was to investigate the relation of the *H*-reflex and ankle jerk by recording nerve potentials during these reflexes.

Fifteen normal subjects were examined. Nerve action potentials were recorded with bipolar non-insulated needle electrodes placed in proximity to the tibial nerve in the upper popliteal fossa and the sciatic nerve in the upper thigh, on stimulation of the posterior tibial nerve low in the popliteal fossa. Simultaneous recordings of the muscle action potential from the calf muscles were made with bipolar subcutaneous needle electrodes fixed in position over the thickest part of the muscle and tendon. The stimulus intensity was increased in stages from that sub-threshold for the reflex to that supramaximal for the direct motor response. The recording electrodes were kept in position and an angle jerk elicited using a reflex hammer with a built-in micro-switch which closed a circuit on percussion and triggered the sweep of the oscilloscope.

Centripetal nerve volleys were frequently recorded at a stimulus intensity sub-threshold for the reflex response (Figs. 1a, 2a). When the afferent volley reached a critical magnitude, an *H*-reflex could be evoked by the Jendrassik manoeuvre, demonstrating that the low-threshold proprioceptive afferents engaged in the two-neurone reflex were contributing to the volley. With increasing stimulus intensity the *H*-reflex first increased in size, and then decreased in size with the development of the direct motor response. The simultaneously recorded nerve potentials showed a progressive increase in amplitude. It is likely that the increase in size of the nerve potential with

Fig. 1. Recording for nerve potentials in the high popliteal region on electrical stimulation of the posterior tibial nerve in the popliteal fossa (a), and on evoking the ankle jerk by mechanical tap of the Achilles tendon (b). The response from the calf muscle is recorded simultaneously.

increasing stimulus intensity is due to excitation of additional afferent fibres and to motor fibres antidromically stimulated. At high-intensity stimulation additional nerve potentials of longer latency were sometimes recorded. These later nerve potentials were not related to the reflex *per se* and were probably due to stimulation of slower conducting fibres.

In no instance when the same electrodes were in position was a nerve potential recorded on tendon tap when a maximal ankle jerk was being evoked (Figs. 1b and 2b).

There is thus a basic difference in the character of the afferent volleys subserving the two reflexes; and the most apparent explanation is that the proprioceptive volley on tendon tap is dispersed, whereas that on *H*-reflex is summated. A summated nerve volley has been recorded from the dorsal root or mixed nerve in cats on single-shock stimulation of low-threshold afferents in the peripheral nerve¹¹, whereas briefly stretching the tendon of a muscle by means of a solenoid resulted in a succession of imperfectly synchronized afferent discharges¹². The occurrence of a centripetal nerve volley below threshold for the electrically evoked reflex indicates the need for spatial summation before the monosynaptic reflex discharge develops; while on tendon tap the motoneurons might be facilitated by the afferent volleys early in the stretch and fired by later components of the afferent stream¹². Thus, on one hand, spatial summation is involved primarily; whereas, on the other, temporal summation is also complexly influenced by firing from other muscle afferents (group 1b, 2 fibres). It is therefore possible that the relatively integrated response of a given population of motoneurons may be different in the two instances. Such a difference would complicate the inference regarding

fusimotor function by the relationship of changes in the electrically and mechanically evoked reflexes.

PHARMACOLOGY

A New, Active Metabolite of 'Miracil D'

'MIRACIL D' ('Lucanthone', I)¹ is an orally active schistosomicidal drug which is of limited value in the treatment of human *S. haematobium* and *S. mansoni* infections². For a variety of reasons it was thought that the effects of this agent were mediated through a therapeutically more active metabolite. A number of abortive attempts have been made to identify and isolate this substance. The latest and most thorough investigation was carried out by Strufe³, who found that the drug underwent extensive metabolic transformation in all species studied. The major urinary metabolite in the mouse proved to be the sulphone (II), while the monkey furnished the sulfoxide (III) and man excreted a 'chromopeptide', a complex of III with polypeptide. It was concluded that none of the above 'Miracil D' derivatives qualified as the elusive active agent.

We have found that the organism *Aspergillus sclerotiorum* converted 'Miracil D' to a mixture of new substances, the structures of which were established by appropriate chemical and spectroscopic methods⁴. The major transformation product was the hydroxymethyl compound IV (hycanthone) accompanied by smaller amounts of the aldehyde V.

The outstanding chemical property of IV is its extreme sensitivity to acid. When exposed to the action of mineral acid at moderate temperature it is largely converted to a water-soluble neutral material which is probably a polymeric quaternary ammonium salt.

- I $R = \text{CH}_3$, $Y = \text{S}$, $X = \text{H}$
 II $R = \text{CH}_3$, $Y = \text{SO}_2$, $X = \text{H}$
 III $R = \text{CH}_3$, $Y = \text{SO}$, $X = \text{H}$
 IV $R = \text{CH}_2\text{OH}$, $Y = \text{S}$, $X = \text{H}$
 V $R = \text{CHO}$, $Y = \text{S}$, $X = \text{H}$
 VI $R = \text{CH}_3$, $Y = \text{S}$, $X = \text{Cl}$
 VII $R = \text{CH}_2\text{OH}$, $Y = \text{S}$, $X = \text{Cl}$

The outstanding bio-logical property of IV is its high schistosomicidal activity when administered *per os* or intraperitoneally to experimentally infected hamsters. When tested according to the procedure of Berberian and

Fig. 2. Recording for nerve potentials in the upper thigh. *a* and *b* as in Fig. 1

Freele⁵ the five-day ED_{50} of hycanthone (IV) was 0.78 mg/kg (*per os*). The corresponding value for 'Miracil D' was 8.0 mg/kg (*per os*). Intraperitoneally the single dose ED_{50} of IV was 0.8 mg/kg.

The high therapeutic activity of IV when given by either route led us to suspect that it may be the active metabolite of 'Miracil D'. The acid sensitivity of IV could explain why it had escaped detection by previous investigators. Accordingly, monkeys were medicated with a total dose of 150 mg of I and the urines were collected over a 48-h period. These were carefully extracted, avoiding acid treatment at every stage and the extracts were examined by means of thin-layer chromatography. In agreement with Strufe's findings the sulphoxide (III) was the major metabolite; only traces of IV were detected. However, when the urine extracts were incubated with glucuronidase prior to thin-layer chromatography, a substance identical with IV (R_F value in several systems, ultra-violet spectra, sensitivity to acid, etc.) proved to be a major component of the mixture.

Kikuth and Gönner⁶ reported that 'Miracil D' was relatively less active in mice than in monkeys infected with the same strain of *S. mansoni*. After glucuronidase treatment the presence of IV was observed in the urine of mice medicated with I, but to a much lesser extent than in the case of the monkey. The same authors also stated that the 6-chloro derivative, VI, was active in mice but not in monkeys. In keeping with this observation it was found that after medication with VI, the glucuronide of VII was present as a major metabolite in mouse urine but only in trace amounts in monkey urine.

These findings support the hypothesis that the hydroxymethyl derivative IV is the important biologically active metabolite of 'Miracil D'. In a discussion of structure-activity relationships in the 'Miracil' series, Gönner⁷ noted that the presence of a 4-methyl group is an absolute requirement for biological activity. The reason for this now becomes clear.

Pronethalol-induced Reversal of Adrenergic Vasodepression

SEVERAL substances have been described as causing reversal of the adrenergic vasodepression observed after blockade of α -receptors, adrenaline reacquiring its usual pressor action. However, when tested in animals treated with long-acting, potent and almost irreversible adrenergic blocking drugs like the β -haloalkylamines dibenamine and phenoxybenzamine, only some pressor agents as, for example, ephedrine, vasopressin, methoxamine, phenylephrine and barium chloride¹⁻³ provoke with regularity negation of adrenergic blockade. In an attempt to investigate the mechanism of this anti-adrenolytic action further, we used the β -adrenergic blocking drug, pronethalol ('Nethalide', 'Alderlin', ref. 4) and made the unexpected finding that it also causes restoration of the pressor action of adrenaline, when injected after blockade of α -receptors.

Cats weighing 2.7 to 3.8 kg and dogs weighing 6.0 to 13.8 kg were anaesthetized with pentobarbitone sodium (30 mg/kg) or chloralose (0.1 g/kg); blood pressure was recorded with mercury manometers, contractions of the nictitating membrane with a frontal writing lever and heart rate with a direct writing electrocardiograph (lead II); plasma potassium was measured in samples of arterial blood using a flame photometer. Suitable doses of adrenaline, noradrenaline and isoprenaline (2.5 to 10 μ g/kg), graded in geometric progression, were injected before adrenergic blockade, 30 min after phenoxybenzamine (5 or 10 mg/kg) and again after pronethalol (5 mg/kg); the latter drug was given by slow intravenous infusion, in 20 min, in order to minimize the fall in blood pressure caused by its rapid injection.

After adrenergic blockade by phenoxybenzamine, adrenaline and isoprenaline had purely depressor effects and the pressor response to noradrenaline was greatly reduced, abolished or reversed to a slight hypotension. Pronethalol caused reversal of adrenaline, augmentation of the residual pressor effect of noradrenaline (or reversal, in the cases in which noradrenaline caused, after phenoxybenzamine, a hypotensive response) and reduction or abolition of the depressor effect caused by isoprenaline; in a cat, isoprenaline even produced, after pronethalol, a monophasic rise in the blood pressure. This anti-adrenolytic action, exhibited by pronethalol, is clearly shown in Fig. 1; it was entirely reversible, its duration never exceeding 2 h, and could be restored by repeating the dose of pronethalol.

Dose-effect curves show that, after pronethalol, adrenaline never re-acquired the pressor potency it exhibited before establishment of adrenergic blockade of α -receptors and that the slopes of the curves are significantly different: before phenoxybenzamine the curves are steeper than after pronethalol. Much the same applies to noradrenaline, which behaved in a parallel fashion. Partial restoration of the pressor action of adrenaline, as already described, was accompanied by a return of the contractions of the nictitating membrane, which had been abolished by phenoxybenzamine; however, the effects of adrenaline on the membrane were much smaller than prior to adrenergic blockade and the restorative effect of pronethalol on the blood pressure responses to adrenaline was disproportionately more marked. During the pressor responses to adrenaline, observed after pronethalol, there was neither increase in heart rate nor a return of the increase in plasma potassium, which had been abolished by phenoxybenzamine.

Recently, Karim⁵, reporting results obtained with an experimental design similar to our own (anaesthetized cats, treated with phentolamine or phenoxybenzamine and pronethalol), mentioned that the depressor effect of noradrenaline injected after blockade of the α -receptors was abolished by pronethalol; however, he used very low doses of noradrenaline (and adrenaline) and could therefore not observe the reappearance of the pressor response, which, in our experience, is seen when doses of the order of some μ g/kg are used.

Drug-induced return of adrenaline hypertension after blockade of adrenergic α -receptors has been explained by assuming that adrenaline causes the heart to beat more frequently and more forcefully, ejecting a greater volume of blood into a constricted vascular bed. Reversal of adrenergic vasodepression would be due to an increased cardiac action working against an increased peripheral resistance (Levy and Ahlquist¹, Sutherland, Ahlquist and Ogden⁶, Levy⁷), and the same explanation has been offered for isoprenaline reversal, which often occurs under the same experimental circumstances. However, this assumption has been challenged by other work, showing that the postulated increase in cardiac action does not occur and that isoprenaline is not devoid of vasoconstrictor effects; the hypothesis of a vascular point of action fits the facts better (Osswald and Guimarães¹¹, Butterworth⁸). The

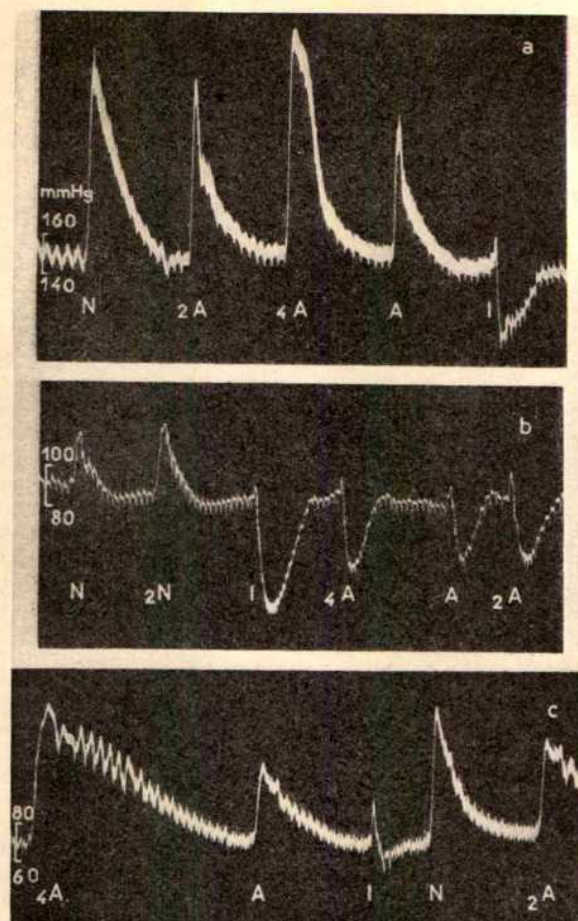

Fig. 1. Blood pressure of dog, 6 kg, pentobarbitone anaesthesia. N = noradrenaline 2.5 μ g/kg; 2N = noradrenaline 5.0 μ g/kg; A = adrenaline 1.25 μ g/kg; 2A = adrenaline 2.5 μ g/kg; 4A = adrenaline 5.0 μ g/kg; I = isoprenaline 5.0 μ g/kg. Between upper (a) and middle record (b), phenoxybenzamine 10 mg/kg was injected. The lower record (c) was obtained after injection of pronethalol 5 mg/kg.

occupied by the blocking drug. Further experimental evidence for this view has been described⁹. If this hypothesis is correct, pronethalol causes reversal of adrenergic vasodepression by blocking the receptors the activation of which causes the vessels to dilate (β -receptors) and therefore makes the free α -receptors available for interaction with catecholamines, that is, those not already blocked by phenoxybenzamine. The following facts seem to fit this explanation well. First, adrenaline never reacquires its full pressor effect; secondly, the return of adrenaline hypertension is accompanied by the reappearance of evident although rather small contractions of the nictitating membrane; thirdly, dose-effect curves of adrenaline and noradrenaline were significantly different from those observed before adrenergic blockade, being displaced to the right and flatter. If the suggested mechanism of action is true, these modifications should be expected to happen, as they actually did. Further work is necessary, however, to confirm the validity of the present hypothesis.

Inhibition of Anaphylactic Release of Vascular Permeability Factor or Histamine by Specific Protease Inhibitor in Tissue Culture

OUR knowledge of the cellular mechanism of histamine release in anaphylaxis is imperfect; there are several controversial hypotheses^{1,2}. The difficulty is due partly to the lack of a specific metabolic inhibitor for the enzymatic reactions activated by the antigen-antibody reaction. By the use of cultured cells, we obtained the rapid activation of a heat-labile, specific SH-protease (Arthus protease) in the early stage of the reaction and the release of a polypeptide inhibitor of this enzyme at a later stage³⁻⁵. The inhibitor was also isolated from skin lesions during Arthus reactions, and it was highly purified as a homogeneous substance paper-electrophoretically and by ultracentrifugation⁶. Its molecular weight was approximately 12,500 (ref. 7). It inactivated the cellular SH-protease and papain but had no effect on trypsin and α -chymotrypsin. The inactivation of the proteases by this inhibitor occurred in parallel with a decrease in the titrable SH-groups of the enzyme molecules⁸. We further obtained the release of an immediate antihistamine susceptible permeability factor (PF) and a delayed antihistamine insusceptible PF (Arthus PF)^{9,10} during the anaphylactic reaction. This purified inhibitor has been used to characterize further the enzymatic mechanism of the anaphylactic release of immediate PF and histamine.

Albino rabbits (2-2.3 kg) were immunized with five subcutaneous injections of 3 ml. bovine serum albumin (BSA) (25 mg/ml.; Armcur)⁹. Explants 1 mm in diameter from the omentum of the animals were cultivated in our culture chamber which allowed simultaneous microscopic and chemical observation⁹. After 5-6 days, almost every cell in each culture was a fibroblast-like cell. The cell

former hypothesis, although theoretically acceptable in the case of reversal of adrenergic vasodepression caused by pressor drugs like ergotamine or ephedrine, cannot explain the results reported in this paper. As a matter of fact, pronethalol does not exhibit any pressor effects and, on the contrary, regularly causes a fall of blood pressure; on the other hand, it effectively blocks the positive chronotropic and inotropic effects of catecholamines, as was well demonstrated in previous investigations^{4,9} and also is apparent from our results.

An alternative explanation would be a direct deblocking action of pronethalol on α -receptors occupied by phenoxybenzamine (or its active metabolites) with removal of the α -adrenergic blocking drug from reactive sites, making them once more available to catecholamines. However, this hypothesis is neither in accordance with the mechanism of action of the β -haloalkylamines (which cause a long-lasting, non-competitive, insurmountable blockade) nor with the facts reported in this work: if such a deblocking action existed, catecholamines would reacquire their full pressor action (or even be potentiated, since β -blockade by pronethalol does potentiate adrenaline in animals not treated with adrenergic blocking drugs) and contractions of the nictitating membrane would be restored to their original magnitude. Since experimental evidence does not support this assumption, the following explanation is offered:

Some years ago, Nickerson, Henry and Nomaguchi¹⁰ suggested that adrenergic blockade by β -haloalkylamines causes adrenaline reversal when only a part (up to 50 per cent) of the receptors subserving vasoconstriction is

numbers were $30,000 \pm 4,000$ per culture. The cells were incubated with 1 ml. inhibitor (in Gey's buffered solution, pH 7.2) or 1 ml. Gey's for 1 min, and after sufficient washing they were incubated with BSA (20 mg/ml. in Gey's) or 1 ml. BSA containing the inhibitor at the same concentrations for 14 min. Each culture fluid sample taken was tested for its histamine content¹¹ and PF effects¹². PF effects were shown by the amount of pontamine blue extracted; immediately after intradermal injections of 0.1 ml. samples the animals were given intravenous dye, 60 mg/ml. as a 5 per cent solution in 0.425 per cent saline, and killed 30 min later. The same type of experiment was performed with *N*-ethylmaleimide, di-isopropyl fluorophosphate (DFP) or soybean trypsin inhibitor (SBTI; Novo).

Table 1. INHIBITION OF ANAPHYLACTIC RELEASE OF IMMEDIATE PF AND HISTAMINE BY PROTEASE INHIBITOR

	Present throughout	Dye leakage (μ g)	Histamine release (ng/ml.)
Inhibitor	None	14.3 (0)	43.0 (0)
"	2 mg	5.6 (61)	14.0 (67)
"	0.5	6.7 (53)	15.0 (65)
"	0.1	10.0 (30)	28.9 (32)
Pretreatment inhibitor	None	14.3 (0)	43.0 (0)
"	2 mg	nt	nt
"	0.5	7.4 (48)	14.8 (65)
"	0.1	10.4 (27)	25.5 (39)

The values in parentheses present each inhibition per cent.

Table 1 shows that the release of immediate PF (as indicated by dye leakage) or histamine by the specific antigen was greatly diminished by our inhibitor. Its inhibitory effect seemed maximal at a concentration of 0.5 mg/ml. It was noteworthy that this inhibitor itself induced no morphological change in the cells when tested by phase-contrast microphotography; and characteristic early morphological changes by the antigen occurred independently of the presence of the inhibitor. The changes were characterized by decreased motion of cytoplasmic processes, decreased pinocytosis, and decreased cytoplasmic flow, but no morphological change in the mitochondria, Golgi bodies and nuclei of the cells was observed at the time of release of immediate PF and histamine. By a pinocytotic mechanism, the inhibitor was probably taken up by the cells prior to adding antigen, but its uptake was suppressed by apparently decreased pinocytosis immediately after antigen application. Accordingly, it seemed reasonable to assume that the inhibitor, which had been taken up by the cells, inactivated specially the intracellular antigen-antibody reaction activated SH-protease (Arthus protease) and resulted in the prevention of release. It did not affect the action of immediate PF and histamine⁹. Little difference in inhibition was observed when the inhibitor was present at the time of addition of antigen or when it was washed before adding antigen. Mongar and Schild¹ suggested the possible involvement of an intracellular cathepsin in histamine release.

In view of the inhibitory effect of *N*-ethylmaleimide on anaphylactic release of histamine in chopped guinea-pig lung¹³, this SH-blocking agent was assayed for histamine release from the cells (PF effect of culture samples was not examined because of permeability-inducing activity of this agent itself). The inhibition by this agent was 95 per cent complete at 10^{-3} M, 51 per cent at 10^{-4} M and 0 per cent at 10^{-5} M. No difference in the inhibition was seen when this agent was present at the time of antigen addition or when it was washed before adding antigen. In spite of such inhibitory effects, *N*-ethylmaleimide seemed unsuitable for the present experiments; it induced rapidly marked morphological changes in the cells even in low concentration (10^{-5} M); there was seen a complete stopping of the motion of cytoplasmic processes and mitochondria and of cytoplasmic flow. Characteristic early morphological changes by the antigen, therefore, could not be detected even when *N*-ethylmaleimide was washed before antigen addition, because of the irreversible changes produced.

DFP was also effective in preventing histamine release in chopped guinea-pig lung, suggesting an involvement of a chymotrypsin-like enzyme in the reaction¹⁴. The inhibition by DFP of histamine release from the cells was 67 per cent complete at 10^{-2} M, 40 per cent at 10^{-3} M and 16 per cent at 10^{-4} M. The inhibition was less marked when DFP was washed before antigen addition; 56 per cent, 21 per cent and 7 per cent, respectively. This agent seemed more toxic to the cells; it induced rapidly marked degenerative changes in the cells. In addition to the changes described above, there occurred an irreversible granulation and vesiculation of mitochondria, retraction of cytoplasmic processes and blister formation from the cell surface even at low concentration (10^{-5} M).

Accordingly, the characteristic features induced by the antigen could not be ascertained even when DFP was washed before antigen addition. DFP also seemed unsuitable for the present experiment. No inhibition of histamine release was obtained with SBTI.

In conclusion, our Arthus protease may play an integral part in the cellular mechanism of immediate PF and histamine release. However, the steps leading to the anaphylactic release are presumably multiple and there is no reason to assume that the characteristics of this reaction are due to the properties of a single enzyme.

We thank Prof. H. O. Schild, University College, London, for his advice and Dr. K. Udaoka for his assistance. This work was supported by grants from the Japanese Ministry of Education and U.S. Army Research and Development Group Far East (DA-92-557-FEC-35779).

PATHOLOGY

A Screening Test for Substances inhibiting the Cancer Coagulative Factor

MALIGNANT tissues produce a thermolabile coagulative factor which diffuses out of cells and lays down fibrin¹⁻³. Tumours have little fibrinolytic activity and the unresolved fibrin around them leads to the growth of connective tissue, blood vessels, and lymph vessels, which form the stroma of the tumour and help the invasion of healthy tissues². Four fractions of the cancer coagulative factor have been identified⁴. Three of these are also present in placental chorion, but only very little of one fraction is found in a few normal tissues⁴. It has been known for some time that watery extracts of placenta have a thromboplastic activity⁵⁻⁷ and that placental extracts cause multiple blood clots when they are injected into animals^{6,7}. It seemed probable that the coagulative effects of cancer and chorion are due to similar factors.

The cancer coagulative factor can be inhibited by protamine sulphate *in vitro*⁸ and the growth of experimental mouse tumours can be slowed by protamine sulphate or its derivatives⁹. There is evidence also that pharmaceutical preparations of protamine can sometimes slow down the growth of malignant tumours in man¹⁰⁻¹³. This makes it seem possible that substances inhibiting the cancer coagulative factor could have practical value. Thus it was of interest to find out whether protamine could counteract the toxicity of placental extracts, and whether this could be the basis of a test.

Two types of watery extracts of fresh placentae were obtained. One was produced at room temperature after mashing up the tissue, and it was heat-stable. It was present mostly in amnion, and when injected into the tail vein of mice it caused dyspnoea within 15 sec and death within 1 min, but it had no delayed effects. The other was made as described by O'Meara and Thornes¹⁴. It was extracted under ice from strips of chorion, and its activity was quickly destroyed by heating. Its potency diminished if it stood at room temperature for 5-10 min and for that reason it was always kept on ice and injected cold. It produced dyspnoea 15-60 sec after injection into a tail vein and death within 5 min, though there were some later deaths. This latter extract resembles the cancer coagulative factor⁴ and it is the one used throughout the tests. Examinations after death showed that both extracts caused multiple blood clots in the lungs.

Table 1. NUMBERS OF MICE PROTECTED FROM LETHAL EFFECTS OF CHORION EXTRACTS

Substance	Dose (mg/kg body-wt.)	Test substance Survived	Test substance Died	Controls Survived	Controls Died	Significance <i>P</i> (2 α)
Protamine sulphate	33	11	3	0	15	0.00002
'Prolothan G'	33	5	0	0	5	0.008
Dextran sulphate	667	14	2	3	16	0.00005
'Eblimar'	1,000	12	1	2	13	0.00007
Plasma ultrafiltrate	100	4	10	0	15	0.08

Experiments were carried out on male and female white mice bred at the Evans Medical Research Laboratories; but tests with white mice from Glaxo Laboratories did not show any differences between breeds, nor was there any evidence of sex difference. All the animals weighed 16-18 g. Each mouse was accurately weighed immediately before the injections. The LD_{50} of chorion extracts injected into tail veins was estimated on the basis of deaths within 5 min. Extracts causing any death in less than 15 sec or with an LD_{50} of more than 3 ml./100 g body-wt. were rejected. Test substances were given in doses of $1/3 LD_{50}$, as experience had shown that higher doses could cause confusion between the ill effects of the test substance and those of the chorion extract. The test substances were made up in 0.9 per cent NaCl solution and given in volumes of 0.5-2 ml./100 g body-wt. The test solution, or an equal volume of 0.9 per cent sodium chloride solution, was injected into tail veins of alternate mice 60 sec before injecting an LD_{50} of chorion extract. The numbers of survivals and deaths were expressed in 2×2 tables and the exact probability of the difference between treated and control mice was calculated, taking $P < 0.05$ (2 α) as significant.

Table 1 shows that there was significant protection with protamine sulphate and with a neutral solution of protamine in glucose ('Prolothan G') suitable for use in man, both from clupein. Significant protection was also obtained with large doses of high-molecular-weight dextran sulphate (Glaxo), and a degraded carrageenan ('Eblimar', Evans Medical)¹⁵. Ultrafiltrate of lamb plasma obtained through a 50 Å filter gave some protection; but this was not significant. Among substances that were ineffective were histone from fowl erythrocytes and from calf thymus, spermine and some of its derivatives, low-molecular-weight dextran ('Dextran 40'), and several synthetic guanidine derivatives, all in doses of $1/3 LD_{50}$.

These results support the view that the effect of protamine on malignant tumours could be due to an inhibi-

tion of the cancer coagulative factor^{10,11}. The test can be used as a screen for inhibitors of the cancer coagulative factor, though, of course, it cannot provide proof of anti-tumour activity.

Distribution of the Intestinal Factor of Normal Mice which inactivates Murine Virus Hepatitis

THE ability of the intestinal content and intestine of normal mice to inactivate murine hepatitis virus (MHV-3) was recently reported¹. The present paper deals with the localization of this activity in different sections of the intestine and in separate strata of the intestinal wall. The distribution of the inhibitor has also been studied in mice of varying ages, and in various tissues of mice, as well as in the intestine of several other species. The interaction between the inhibitor and the virus has also been studied *in vitro* at 37° C and at 2° C.

In order to test the effect of the different materials on virus infectivity, the following procedure was used: the virus², stored at -70° C as a 10 per cent suspension ($LD_{50} = 10^{-8.1}$), was used in 10-fold dilution from 10^{-1} to 10^{-9} . Depending on the experiment, several series of these dilutions were prepared to contain a homogenate of the different materials in final concentration of 10 per cent. One more series was used as a control (no homogenate added). All samples, after addition of antibiotics, were incubated at 37° C for 90 min and frequently shaken. Virus levels were then determined in each sample according to the method of Reed and Muench³.

Table 1 shows that the inhibitory activity is predominantly present in the first section of the small intestine, and decreases in the middle and still further in the lower sections. The large intestine possesses a certain ability to inactivate the virus, although to a lesser extent than the small intestine. Table 2 shows that the intestinal mucosa is the most effective tissue in inactivating the virus, whereas the rest of the intestine (without the mucosa) displays a lower activity. The inactivating power varies with the age of the mouse, reaching a maximum in adult-

Table 1. EFFECT OF DIFFERENT SECTIONS OF INTESTINE OF ADULT MICE* ON MHV-3 VIRUS INFECTIVITY

Virus + middle portion (13 cm) of small intestine	3.0
Virus + last portion (13 cm) of small intestine	4.1
Virus + large intestine	5.1

* N.M.R.I. strain.

Soon after killing the animals the intestine was thoroughly washed to remove any faecal debris. Mice were injected intraperitoneally (0.1 ml.) with 10-fold dilution of each material from 10^{-1} to 10^{-9} (10 mice for each dilution). The experiment reported in Table 1 is one of three which gave similar results.

hood (Table 3). As far as the localization in other tissues is concerned, it was found that, besides the intestine, only the stomach, of all the tissues studied, possesses a certain activity (Table 4). In the experiments summarized in Table 5 the intestine of various species of animals, and different intestinal sections from man, were tested. It is evident that, besides the mouse, only the rat possesses, albeit to a lesser extent, the ability to inactivate the virus. No activity was found in horse intestine mucosa. Fig. 1 shows that, at 37° C, the activity increases with incubation time, whereas at 2° C no activity at all could be detected.

From the data presented here, it appears that the principle which inactivates MHV-3 virus is mainly present in the intestinal tract of the adult mouse, and particularly in the first section of the mucosa of the small intestine. Furthermore, it is evident that interaction between the inhibitor and the virus *in vitro* is dependent on temperature.

Work is in progress to determine the chemical nature of the inhibitor and to attain its purification. Preliminary experiments have already revealed the difference between

IMMUNOLOGY

Reaction of Adenine-specific Antibodies with Denatured Deoxyribonucleic Acid

At the present time there is no doubt regarding the role of nucleic acids in carrying genetic information, and their participation in protein synthesis and other biological events is now well known¹. There is therefore considerable biochemical and genetical importance in the availability of specific antibodies capable of reacting with nucleic acids. The production of such antibodies has been described recently as the result of immunization with DNA that had been complexed with methylated bovine serum albumin², by coupling periodate-oxidized nucleotides or nucleosides to proteins³, or by binding uridine-5'-carboxylic acid to a synthetic polypeptide⁴. Such data promise to make the specificity and sensitivity of immunochemical procedures, which have been of great value in the study of other polymers such as polysaccharides and proteins⁵, similarly available for an analysis of nucleic acids.

This communication will report on further observations that support the feasibility of producing antibodies that can react with nucleic acids. It is known that periodate ions are able to attack adjacent hydroxyl groups, cleaving the carbon-carbon bond, yielding aldehydes⁶ which can

react with several other groups such as amines^{7,8}. In our studies adenosine-specific antibodies were obtained by immunizing rabbits with conjugates of periodate-oxidized adenosine coupled to human gamma globulin and albumin, which also had been oxidized by periodate (see Fig. 1).

The conjugates were prepared as follows: 735 mg sodium periodate was dissolved in 20 ml. water; to this solution 184 mg adenosine was added and incubated at 4° C for 12 h. The solution was divided in two 10-ml. portions. To one portion 250 mg of human gamma globulin, dissolved in 5 ml. saline, was added. To the other portion, 250 mg of human albumin dissolved in 5 ml. water was added. Both solutions were incubated at 4° C with stirring for 24 h. During this time a precipitate formed in both solutions. The suspensions were then lyophilized, resuspended and dialysed, and the final volume was adjusted to 10 ml. Since the conjugates were

Fig. 1. Periodate oxidation of adenosine, and conjugation

Fig. 4. Conjugate albumin-adenosine (IO_4^- , BH_4^-)

insoluble, they could be washed with water or saline and, when desired, rendered soluble by the addition of sodium borohydride (amyl alcohol was added to avoid foaming). Soluble preparations were used for precipitation reaction, insoluble preparations were employed in immunization. When conjugates were made soluble the excess of borohydride was eliminated by dialysis.

Figs. 2, 3 and 4 show the ultra-violet absorption spectra of periodate-oxidized adenosine and of the solubilized conjugates. According to the absorption spectra of conjugates and oxidized adenosine, the approximate ratio of adenosine to protein was 20–25:1 for gamma globulin and 10–12:1 for albumin.

For immunization, 0.5 ml. of the suspended insoluble conjugates was mixed with 0.5 ml. of adjuvant (Arlacel-Drakeol 1:9 + 2 mg of *Mycobacterium bovis* per ml.) and injected into the foot pads of rabbits. Two rabbits were used for each conjugate. The animals received five additional intradermal injections at weekly intervals and were bled six days after the last injection.

The sera from the four immunized rabbits precipitated both types (albumin and globulin) of soluble conjugates, but did not react with the heterologous oxidized protein free of coupled adenosine. The four antisera precipitated heat-denatured calf thymus and salmon sperm DNA as shown in Table 1. As shown in Table 2, the amount of antibody that is precipitated will vary with the source of

BIOLOGY

Experimentation with Plants at Sub-atmospheric Oxygen-levels: Effects of Oxygen Pressure and Salts on Germination of Winter Rye

In a series of recent investigations, it has been shown that plants can be grown in atmospheres with reduced oxygen pressures or in air at reduced total pressure. Germination and seedling growth are in some cases accelerated at sub-atmospheric oxygen levels, and are commonly comparable with these processes in air.

In spite of their essentially normal growth and gross morphology, a number of pronounced changes in biochemical composition^{2,3} and metabolism^{4,5} have been demonstrated. Some experiments have assessed relationships between pO_2 and specific physiological processes such as abscission⁶ or other environmental factors such as heat or cold.

One of the many factors influencing seed germination and seedling growth is salinity. The present paper reports on experiments relating pO_2 and calcium-ion to the effect of saline water on winter rye.

Commercial winter rye seed (*Secale cereale*) (1962 crop) were germinated routinely on filter paper in sterile Petri dishes, containing 25-30 seeds and 10 ml. distilled water.

Seeds were incubated at $25^\circ \pm 1^\circ$ C in constant light (cool white fluorescent, 100-ft. candles). Gas mixtures consisted initially of oxygen plus nitrogen.

Rye is a facultative anaerobe, and a highly competent microaerobe, which germinates somewhat more slowly at $pO_2 = 15$ mm than at higher levels when in distilled water (Table 1). In sodium chloride at 0.25 M, germination at all oxygen levels except 150 mm (air) was reduced to one-half or less relative to distilled water. In 0.75 M, sodium chloride inhibition of germination was complete at $pO_2 = 15$ mm, and higher oxygen pressures permitted only a few seeds to germinate poorly. At 0.1 M, sodium chloride does not inhibit germination. When $Ca(NO_3)_2$ at 0.02 M is added to this level of sodium chloride, germination at $pO_2 = 15$ mm is unaffected. In contrast, at all higher oxygen levels in 0.1 M sodium chloride, the presence of calcium nitrate results in significantly elevated germination. When salinity is raised to 0.25 M, $Ca(NO_3)_2$ has a beneficial effect at all oxygen levels, but is relatively more stimulatory at pO_2 50-100 mm.

The most striking response, however, was obtained at 0.75 M sodium chloride, where germination was completely arrested at $pO_2 = 15$ mm, but proceeds to a slight degree at higher oxygen pressures. At this salinity the calcium effect is seen to be quite large, but quantitatively dependent on the pO_2 .

The response of primary root growth (Table 2) post-germination follows the general pattern seen in germination but differs in some significant details.

(a) An optimum pO_2 of 50 mm in distilled water is indicated, but disappears in sodium chloride solutions.

(b) Marked salt inhibition appears between 0.025 and 0.10 M sodium chloride, which is less than required for inhibition of germination.

Again, increasing pO_2 and $Ca(NO_3)_2$ enhances root elongation, and the calcium-effect is aerobic in character.

Table 1. EFFECT OF OXYGEN PRESSURE AND CALCIUM-ION ON THE GERMINATION OF WINTER RYE IN SALT SOLUTIONS

+ 0.02 M KNO_3	1.1	1.4	0.3	

* Mean length (cm) of roots after 3 days at 25° C based on 35-50 seedlings. L.S.D._{5%} = 0.7 cm.

Table 4. GERMINATION OF RYE SUBMERGED IN AERATED SOLUTIONS

Solution	Ionic strength μ	Germination after 10 days (%)
H $_2$ O	—	89
0.7 M sucrose	—	100
0.5 M NaCl	0.50	15
0.5 M KCl	0.50	21
0.18 M $MgCl_2$	0.54	4
0.18 M $CaCl_2$	0.54	87
0.4 M $CaCl_2$	1.2	28

The effect of calcium nitrate was examined further, assuming that either constituent ion, or the two in concert, could be responsible for reversal of salt inhibition. Accordingly, the effects of several appropriate salts on the extension of roots in 0.10 M sodium chloride were compared (Table 3). At $pO_2 = 15$ mm and 50 mm (optimum for root elongation), only $Ca(NO_3)_2$ had a significant effect, whereas at the oxygen-level of air, both calcium salts were active, the chloride being somewhat more so than the nitrate. Thus, if at lower oxygen levels NO_3^- is serving as an electron acceptor, it apparently can do so only in the presence of Ca^{++} . Conversely, if Ca^{++} acts, conceivably at the membrane, to counteract the effects of excess Na^+ , it also can only do so when NO_3^- is present. Under strictly anaerobic conditions, KNO_3 at concentrations of 10^{-3} to 5×10^{-2} M can stimulate rye germination¹, whereas calcium salts (other than nitrate) ordinarily have no effect.

Calcium salts other than the nitrate can have unique effects in certain rather unusual cases of oxygen-limited germination (Table 4). When rye seeds are submerged in 15 cm of water or 0.7 M sucrose, their germination is slow but otherwise normal and essentially complete. In 0.5 M sodium and potassium chloride, germination is severely suppressed, although these solutions are approximately isosmotic with the sugar. Further, magnesium and calcium chloride are comparable in ionic strength to potassium chloride, yet the magnesium solution is highly inhibiting whereas the calcium solution permits nearly normal germination.

This work was carried out under National Aeronautics and Space Administration contract NASw-767.

Morphactins, a Novel Group of Plant-growth Regulators

IN 1960 some interesting effects of fluorene-9-carboxylic acids on plants were observed at the biological research laboratories of E. Merck AG, Darmstadt, Germany. An intensified research programme on these compounds and on a great many derivatives was initiated by this company, which, during the following years, led to the discovery of a large-numbered group of compounds of substantial interest, some of which show an extremely strong action on the growth and development of plants¹. This particular action has novel and somewhat unique features, and was reported first in 1964 by Schneider².

Compared with the known types of plant-growth substances³, the new fluorene-regulators do not fit into the existing scheme of such growth-regulating activities and, therefore, they really constitute a novel class of plant-growth substances.

Their overall activity is growth retardation, resulting in stunted and often malformed dwarf plants: bushy-stunted growth type or otherwise peculiar habits. Typical symptoms were already briefly summarized². Out of the new regulators, some have a remarkably broad spectrum of activity over a very wide range of concentrations (corresponding to that of the gibberellins), essentially free from phytotoxic side effects. Treated plants often become gradually darker green in colour².

These and other outstanding features established the new group's name, namely *morphactins* (*morphogenetic*

active substances)². A more detailed account on basic work with these compounds will be presented elsewhere⁴.

Fluorene-9-carboxylic acid, basic structure of the morphactins

The broad activity spectrum combined with low phytotoxic side effects to the plants treated, even at high dosage-levels, makes certain members of the morphactins interesting for slowing down the growth of mixed vegetations, where to a certain extent plant coverage of soil is essential for prevention of soil erosion by wind and/or rainfall. These substances, for example, methyl-2-chloro-9-hydroxy-fluorene-(9)-carboxylate, seem to be useful agents for growth retardation and suppression, respectively, for example, along highways, railroads, ditch banks, sporting areas, and even in special perennial crops such as orchards and vineyards, too. In this connexion, it should be mentioned that residual activity of the new compounds in soils is strongly limited; these will be broken down in most soil types within a few weeks after application, mainly by microbial attack^{5,6}.

Besides growth retardation, other members of the group offer new possibilities for broad-spectrum control of weeds in cereals and grassland (pastures and meadows), because of synergistic action with known herbicides of different kinds¹, such as phenoxy compounds^{5,7}. For example, suitable formulations containing the morphactins *n*-butyl-9-hydroxy-fluorene-(9)-carboxylate or salts of 9-hydroxy-fluorene-(9)-carboxylic acid together with MCPA and/or 2,4-D and/or another phenoxy compound in optimal proportions give good control of a variety of weeds which are difficult to control, such as *Galeopsis*, *Galium*, *Stellaria*, *Polygonum*, *Matricaria*, *Chrysanthemum*, *Lamium*, *Veronica*. Proper timing of application, that is to say, spraying at early developmental stages of the weeds, is essential for complete success^{5,7}.

Moreover, besides growth retardation and broad-spectrum weed control, morphactins offer some other features and advantages, which make this new experimental group an attractive one. Toxicity in mammals and fish is very low, for example, in rats (Wistar) LD_{50} oral acute is greater than 5,000 mg/kg body-wt.⁷

In the meantime research on a variety of fundamentals in plant growth and development and also on a range of practical aspects is in progress. Basic information on the morphactin group is now available⁷.

Winter Scale Rings in Lates niloticus (Pisces: Centropomidae) from Lake Chad

THE formation of scale rings in tropical fishes has usually been ascribed to some form of physiological stress producing a temporary check in the growth-rate. Holden¹ thus proved that in *Tilapia* spp. from Lake Victoria ring

* Showing percentage occurrence according to the width of the zone between the most recently formed ring and the margin of the scale.

formation is associated with spawning; Johnels² and Daget³ both correlated the annual rings which occur in many West African savannah species of fish with adverse environmental conditions, particularly food shortage, occurring during seasonal drying-up of the rivers. It appears that scale rings usually formed under tropical conditions are not strictly comparable with those of temperate species, which are laid down as a consequence of differences between summer and winter growth-rates, and where change in temperature is the most important factor.

It is therefore interesting to record that during a recent examination of *Lates niloticus* (Nile perch) in Lake Chad (lat. 13° 30' north) genuine 'winter' rings were laid down in immature fish. The annulations consist of breaks in an otherwise regular series of concentric circles on the anterior half of each scale traceable posteriorly to marked lines of discontinuity near the etenoid sector of the scale. An analysis of scale margin data for immature males (Table 1) shows that in a high proportion of fish the scale ring was formed between December and March. Water temperatures fell during this period to as much as 12° C below the maximum temperatures recorded during June and September, the warmest months of the year. It seems reasonable to correlate the formation of scale rings with a temperature drop of this magnitude.

Results indicate that rings are usually formed in three successive winters before males of *L. niloticus* mature at a total length of approximately 50 cm. Preliminary investigations suggest that age determination in mature fish may be complicated by the formation of spawning rings in addition to the annual winter rings.

Technique for the Removal of the Brain in Bats

In public health investigations it is essential that animal hosts and reservoirs be correctly identified. Specialists, particularly mammalogists, are usually willing to identify specimens collected in return for retaining all or a portion of the mammals submitted, especially if the specimens, such as bats, come from a zoologically interesting area, are rare in collections, or might present some challenging taxonomic problem. Since there is an increasing interest in the public health importance of bats (such as their involvement with rabies), countries which have not yet made surveys of their bat populations for the incidence of rabies are being encouraged to do so (Expert Committee on Rabies—Fourth Report, W.H.O. Tech. Rep. Ser. No. 201, 1960). For the purposes of accurate identification, the head is the most important part of the body to the mammalogist, while its contents are of paramount importance to the epidemiologist. The conventional laboratory techniques used for brain tissue removal in rabies diagnosis

Fig. 1 Brain tissue may be hypodermically withdrawn through foramen magnum

Fig. 2 Cranium exposed after longitudinal incision made along head midline

(W.H.O. Monogr. Ser. No. 23, 1954, and U.S. Public Health Service Pub. No. 568, 1957) frequently mutilate the skin and skull and not only make identification difficult but ruin the specimen for museum purposes.

While investigating bat ecology and rabies in Trinidad, we devised methods satisfactory to both mammalogist and virologist, removing brain tissue with little or no head damage. We found it unnecessary to open the calvaria, or brain case, either on very small bats or on those with specialized attachments between the ears, or unusual glandular structures on the top of the head, since sufficient brain tissue may be hypodermically withdrawn through a needle inserted into the foramen magnum without skull damage (Fig. 1). The optimum needle size can be determined with a little practice. It is sometimes necessary to agitate the needle or even inject a drop of physiological saline solution within the brain case to loosen the brain tissue and permit easier suction into the syringe. A needle with a dull tip is safer to use than a sharp one; for it makes it possible to probe the cranial interior without danger of penetrating the bone with the sharp point. In our experience, freshly killed warm specimens, or those that have been allowed to warm up after refrigeration, are easiest to manipulate.

If a study calls for the removal of the entire brain, our alternative method does damage the skull, but not necessarily beyond repair, if care is taken in the process and cutting instruments are kept sharp. The bat is held in the palm of the hand with its back exposed. With the ball of the thumb, the skin at the base of the head and close to the cervical and interscapular fossae is pushed forward over the top of the head toward the snout, and held taut. It may be necessary to limber the skin by moving it back and forth. Then as much skin as possible is moved forward and tightly held. With a sterile scalpel, a longitudinal incision is made along the midline of the head, beginning anteriorly just in front of the eyes and extending posteriorly to the base of the skull, cutting through the skin and fasciae, finally exposing the cranium. In some of the larger phyllostomid bats such as *Phyllostomus*, *Vampyrus* and *Artibeus*, it is necessary to dissect the temporal muscles away from both sides of the cranium and reflect them laterally before exposing the bone (Fig. 2). With sterile pointed-tipped scissors, preferably with curved blades, a transverse cut is made just above the eyes through the frontal area at the interorbital constriction. The bone of the skull is then incised on both sides, cutting posteriorly through the squamous portion of the temporal bone (taking care not to destroy the zygomatic arch) above the

auditory bulla, through the base of the parietal bone to the base of the lambdoidal crest (Fig. 3). Do not cut through the crest. The calvaria may be then lifted from the frontal cut and turned back, using the lambdoidal crest as a hinge, exposing the brain. With fresh sterile scissors, the brain may be severed from its site and lifted out entire, using the partially opened curved blades as a rest, and placed in a container (Fig. 4).

In order to assist the mammalogist in his task of identification, and to preserve a good museum specimen, it is important that the calvaria be carefully replaced along the incisions, the temporal muscles neatly returned to both sides of the cranium, and the integument gently eased backward over the head and returned to its original placement so that the initial incision lies close to or over the cervical or interscapular fossae. If necessary, this incision may be used to remove the brown adipose tissue which lies within the two fossae (Fig. 5).

Extreme caution should be taken by persons opening bat heads. Rubber gloves should be worn, and careful operative technique employed. Whether the procedure is carried out in the laboratory or in the field, sterile instru-

ments should be used to reduce the chances of bacterial contamination.

MICROBIOLOGY

Micro-organisms associated with Dead Insect Larvae in Nigeria

SPECIMENS of dead soil-inhabiting insect larvae (*Anomala* sp. and *Heteroligus* sp.) and noctuid larvae were supplied to me or collected by me for microbial isolations. Larvae of *Anomala* and noctuids were collected from fields on Moor Plantation, Ibadan, while yam-beetle larvae (*Heteroligus* sp.) were collected around Benin and Onitsha. *Anomala* and *Heteroligus* larvae were either dead on being dug up in the field or died while under storage in moist soil in the laboratory. Stored larvae were adequately provided with food (for example, pieces of yam) and aeration.

When a visible fungus growth appeared on the larvae, a pair of fine flame-sterilized forceps was used in picking out spores and/or hyphae and incubating them at 30° C on glucose-yeast extract agar (GYA) containing 2 g NaNO₃, 1 g KH₂PO₄, 0.5 g MgSO₄, 0.5 g NaCl, 5 g yeast extract (Difco), 10 g glucose, and 15 g agar in a litre of water. After picking out surface fungal propagules and in cases where no surface-growth was evident, the larvae were surface-sterilized with 0.1 per cent HgCl₂ in 70 per cent alcohol followed by thorough washing in sterile water¹. The larvae were then cut into small pieces under sterile conditions and incubated on GYA or nutrient agar at 30° C. The micro-organisms isolated, the source and the number of larvae from which they were isolated are shown in Table 1.

It might be expected that the micro-organisms would 'clear' chitin² (that is, cause a disappearance of finely ground chitin particles incorporated into an agar medium), since chitin makes up 20–30 per cent of the insect exoskeleton³. Only *Aspergillus giganteus* and the bacterium, however, cleared chitin after 12 and 13 days incubation respectively on chitin agar² at 30° C. Similar observations of the inability of insect-pathogenic fungi to clear chitin have been made with respect to *Beauveria*⁴. When a washed suspension of the bacterium was mixed with soil in which larvae of *Anomala* sp. were placed, as many larvae died each fortnight in the control as in the soil with the bacterium. When, however, the bacterium was introduced with a micro-injector through the integument into the body cavity of ten larvae, all ten died within 24 h, whereas all the controls (injected with equivalent

volumes of sterile distilled water) survived. Similar results were obtained when the experiment was repeated. Insects were kept in moist soil in the dark at room temperature during the tests. The bacterial inoculum was prepared by scraping off bacteria from a 6-day slope, and making it up in 10 ml. of sterile distilled water; 0.005 ml. of the suspension was used.

Except for the bacterium, no valid suggestion can be made that the micro-organisms recorded in this experiment were responsible for the death of the larvae, although some of the fungi (for example, *Metarrhizium*) may have been pathogenic, symbiotic or saprophytic in or on the living insect; they may, on the other hand, have developed as saprophytes on larvae which have died from other causes.

The value of this communication appears to me to lie in the reporting of some of the fungi for the first time in Nigeria, in the unusual ecological niches provided for the micro-organisms by the larvae and in the possibility that some of the isolates may prove useful as agents in the biological control of insect pests.

I thank Dr. M. L. Jerath and Mr. S. A. Adeyemi for providing respectively the soil larvae and some of the noctuid larvae, Miss Evelyn Page for assistance, and the staff of the National Collection of Industrial Bacteria for examining the bacterium.

A Rapid Screening Test for Transfer Factors in Drug-sensitive Enterobacteriaceae

In a recent article¹ a technique was described for screening drug-sensitive strains of Enterobacteriaceae for the presence of transfer factors. This entails the incorporation of each strain under test in a mixture consisting of an intermediate recipient, containing a non-transferring resistance determinant (*R*-determinant)^{1,2} and a final recipient which is drug-sensitive and devoid of a transfer factor. If a test strain carries a transfer factor, this migrates into the intermediate recipient and unites with the *R*-determinant to form an *R*-factor which then transfers into the final recipient.

The intermediate strain used in these tests was *Salmonella typhimurium* type 36 carrying *S'*, an *R*-determinant for streptomycin resistance, but unable to transfer it because of the absence of the transfer factor Δ with which the *R*-determinant was originally associated¹; this strain is referred to as *36S'* Δ -. The final recipient was *Escherichia coli* K12F-. The test strains and the intermediate and final recipients were inoculated separately into nutrient broth, and incubated with agitation for 5-6 h at 37° C. 3 ml. of the culture of each test strain was then mixed with an equal volume of *36S'* Δ - and incubated without agitation for 2 h at 37° C. This provided any transfer factor present in the test strains with an opportunity to transfer to *36S'* Δ - to form a streptomycin *R*-factor. 3 ml. of the K12F- broth culture was then added and the mating mixtures were incubated overnight at 37° C. The following morning, they were streaked in decimal dilutions on streptomycin-MacConkey agar plates on which 0.3 ml. of 01 phage (titre > 10¹¹ particles/ml.) had been spread. These plates were incubated overnight at 37° C. The drug-sensitive donor strains were eliminated by the streptomycin in the medium, and the intermediate *S. typhimurium* recipient by the 01 phage. Thus, only K12F- cells that had

received mobilized streptomycin resistance could grow freely, to produce red, lactose-fermenting colonies.

This screening test may be speeded up by spotting the undiluted mating mixtures, with a loop delivering c. 0.01 ml., on streptomycin-MacConkey agar on which phage 01 has been spread. After incubation, the presence of a transfer factor in a test strain is shown by a growth of lactose-fermenting colonies of K12F- which has received the newly formed streptomycin *R*-factor. A number of drug-sensitive strains may be screened for transfer factors on a single plate in this way. The mating mixtures are stored at 4° C until the results of the spot test are read. Those containing drug-sensitive donor strains giving positive results are then spread in decimal dilutions on streptomycin-MacConkey agar as described earlier, for more precise examination and clonal selection of K12 colonies that have received streptomycin *R*-factors. The characteristics of the respective transfer factors may then be investigated further.

Fig. 1 shows a plate on which a spot screening test for transfer factors has been performed on wild, drug-sensitive strains of *S. typhimurium*.

The contents of the various sectors of the plate shown in Fig. 1 are as follows (phage-types of wild *S. typhimurium* are referred to as types, and K12F- as K12): (1) Type 29 \times *36S'* Δ - \times K12. (2) Type 29 \times *36S'* Δ - \times K12. (3) Type 44 \times *36S'* Δ - \times K12. (4) Type 29 \times *36S'* Δ - \times K12. (5) Type 29 \times *36S'* Δ - \times K12. (6) Type U194 \times *36S'* Δ - \times K12. (7) *36S'* Δ - \times *36S'* Δ - \times K12 (= positive control). (8) *36S'* Δ - \times K12 (= negative control). (9) K12 alone (= negative control).

All the wild strains of *S. typhimurium* were of independent origin and were isolated in 1965.

Mating mixtures 1, 5, 6 and 7 show positive results, that is, the conversion of K12 to streptomycin resistance by transfer of a newly formed streptomycin *R*-factor. The positive control contained as the donor a strain of phage-type 36 of *S. typhimurium* into which the Δ transfer factor alone had been introduced¹. As the test spots receive the undiluted mating mixtures, colonies of the intermediate *S. typhimurium* recipient resistant to phage 01 usually appear. However, when transfer has occurred, the red, lactose-fermenting K12 colonies are easily distinguishable from the yellow, non-lactose-fermenting *S. typhimurium* colonies as Fig. 1 shows.

Controls were also set up of each wild donor strain crossed with K12, to exclude the possibility that streptomycin *R*-factors might be phenotypically masked in the

Fig. 1. Streptomycin-MacConkey agar plate showing the presence of transfer factors in wild, drug-sensitive strains of *S. typhimurium*. The strains represented in sectors 1, 5 and 6 carry transfer factors. Sector 7 contains the positive control (\times c. 0.8).

drug-sensitive donors; these controls were uniformly negative.

The origins of the wild drug-sensitive *S. typhimurium* strains carrying *R*-factors were as follows: (1) phage-type 29; isolated from a turkey (Mundford, Norfolk); (5) phage-type 29; isolated from a chick (Gloucester); (6) phage-type U194; isolated from man (Oldham, Lancashire).

Our tests show that transfer factors unattached to *R*-determinants may be widely distributed in the Enterobacteriaceae. If such factors gain access to strains carrying non-transferring *R*-determinants to which they can become attached, transfer of drug resistance is initiated. This may be the process by which *R*-factors are initially formed. The presence of antibiotics and synthetic antibacterial drugs in the animal hosts parasitized by Enterobacteriaceae possessing these potentialities may accelerate both the initiation and the spread of this type of resistance.

Effect of Incubation Temperature on the Flagellation of Gram-negative Rods

THE primary factor used in *Bergey's Manual of Determinative Bacteriology*¹ for the division of Gram-negative rods into families is the flagellation of the cells. The method has always proved a source of difficulty and has led to much confusion as to the taxonomic position of cultures. This point was well illustrated by Dye², who produced micrographs of cells of a culture of *Xanthomonas trifolii* in which polar or lateral monotrichous and peritrichous flagellation could all be demonstrated.

Coetzee and de Klerk³ have shown incubation temperature to be a factor that could affect the type of flagellation of *Proteus* and *Providencia* cultures. These authors used incubation temperatures of 43°, 37° and 30° C. When re-defining mono- and lophotrichous in terms of a flagella index, Lautrop and Jessen⁴ arrived at their conclusions after examining a collection of pseudomonad cultures, mainly *Pseudomonas aeruginosa*, which were grown at 'room temperature', at 30° or at 10° C. Although they recommended that cultures with intermediate flagella indices should be studied after growth at 10° C, Lautrop and Jessen did not emphasize the influence of incubation temperature on flagellation.

While attempting to classify a collection of 100 cultures of Gram-negative rods which had been isolated from milk, flagella preparations were made from cultures which had been incubated on Oxoid 'Lab-lemco' agar slopes at 30° C. These cultures were found to be lopho-, monotrichous or aflagellate. A number of polar or sub-polar monotrichous cultures were encountered that from their biochemical reactions appeared to belong to the Enterobacteriaceae. The cultures were, therefore, examined for flagellation after incubation at 30°, 22° and 15° C and a few cultures also at 5° C.

The results showed that the use of only one incubation temperature could give rise to errors in assessing both the numbers of flagella and the type of flagellation. Among the pseudomonad group, the non-pigmented culture 369 showed monotrichous polar flagellation at all four incubation temperatures, culture 149 (*Pseudomonas fluorescens* type) was predominantly lophotrichous only at 15° C, while the biochemically similar culture 131 showed lophotrichous cells only at 22° C. Culture 143, a biochemically rather inactive pseudomonad, gave the same proportions of mono- and lophotrichous cells at the four incubation temperatures as did culture 149.

Cultures 119 and 533, which oxidized glucose and gave a positive oxidase reaction, both showed polar monotrichous flagellation at 30° C but peritrichous flagellation at 22° C. The same flagellation effect was shown by culture 466, which failed to ferment glucose and was oxidase-negative.

In the same way, apparently similar fermentative, oxidase-negative cultures showed different types of flagellation after growth at different incubation temperatures. Culture 460, which was monotrichous at 30° C, was peritrichous at 22°, while culture 373 became peritrichous at 15° C. Another fermentative culture (495), which was aflagellate at 30° C, showed predominantly monoflagellate cells at 22° and 15° C but was peritrichous at 5° C. This latter culture showed motility after incubation at 30° C on soft nutrient agar (0.2 per cent agar).

If flagellation is to be retained as the main criterion for the classification of Gram-negative rods, then more emphasis should be placed on the examination of cultures grown under varying conditions before assigning a taxonomic position based on flagellation.

VIROLOGY

Mechanical Transmission of Hop Mosaic Virus

HOP MOSAIC VIRUS (HMV), the cause of a severe disease of the Golding hop varieties, was shown by Paine¹ to be transmitted by the winged form of the damson-hop aphid, *Phorodon humuli* Schr., but transmission by sap extracts has not been reported. This has been accomplished with both concentrated and crude extracts of leaves from plants of sensitive and tolerant hop varieties, by inoculating single-node hop cuttings a few days after removal from the mist chamber where they had formed roots; similar cuttings were used as test plants throughout this investigation. 30-g young leaves from recently infected Golding hop plants were macerated in 150 ml. 0.05 M phosphate buffer, pH 8.3. The sap was squeezed through cotton cloth and clarified by centrifugation for 10 min at 10,000g. The supernatant was centrifuged for 180 min at 70,000g (Spinco L No. 40 rotor at 32,500 r.p.m.). The pellets were resuspended in 3 ml. distilled water and, after the addition of 'Celite', the suspension was used to inoculate young leaves on twenty cuttings of a Golding hop, nine of which became infected.

Later, HMV was transmitted from crude extracts of young hop leaves. Leaf tissue was macerated in phosphate buffer (5 ml. per g); the extract, separated from the fibrous residue by squeezing through cotton cloth and after the addition of 'Carborundum' (400 mesh), was rubbed on leaves of Golding hop, *Chenopodium quinoa*, *Nicotiana clevelandii*, *N. tabacum* var. White Burley and *N. glutinosa*. Three of five inoculated hop plants were infected with mosaic virus. Pale green spots and mottle symptoms developed on some of the inoculated leaves of the *Nicotiana* spp. and *C. quinoa* plants, one of which also developed pale green vein-banding and leaf distortion. However, HMV was recovered only from the *N. clevelandii* plants, all eight of which developed in 5-9 days pale green spots (1-3 mm diameter) with necrotic centres on the inoculated leaves. These plants gradually deteriorated, their leaves became chlorotic and necrotic and many of their roots died. Eighteen days after inoculation leaves from pairs of *N. clevelandii* plants were bulked, macerated in an equal volume of phosphate buffer and sap extracts from each pair inoculated to two Golding hop plants; one extract

Table 1. ISOLATION OF HOP MOSAIC VIRUS FROM *N. clelandii*

Source leaves of <i>N. clelandii</i>		Test plants infected/inoculated	
		Golding hop	<i>N. clelandii</i>
Inoculated	With symptoms	5/6	2/2
	Without symptoms	0/14	0/7
Uninoculated	With symptoms	3/4	4/4
	From plants without systemic symptoms	2/4	4/4

infected both test plants and each of the other three inocula infected one.

The distribution of HMV in *N. clelandii* was examined in ten plants that were inoculated with crude extract from Golding hop leaves. All plants developed primary lesions on some inoculated leaves; systemic symptoms in the form of chlorotic spotting occurred on the later-formed leaves of two plants. Inoculated leaves were harvested after 7 days and uninoculated younger leaves after 6 weeks. Leaves with and without symptoms were macerated separately and the extracts used to inoculate Golding hop and *N. clelandii* plants. HMV was transmitted from inoculated leaves with symptoms whether or not the plant developed systemic symptoms, but not from symptomless inoculated leaves (Table 1).

CYTOLOGY

Cytoplasmic Labelling with Uridine-5-³H in Human Lymphocytes cultured with Phytohaemagglutinin

Hayhoe and Quaglino¹ have reported investigations of RNA metabolism in normal human leucocytes when cultured with phytohaemagglutinin, using uridine-5-³H as a specific precursor of RNA. They found little evidence of cytoplasmic labelling after terminal incubation for 1 h with tritiated uridine (0.5 μ c./ml.), either at 24, 48 or 72 h of culture.

We have been conducting similar investigations with this nucleoside specific activity; 22.4 c./mmole added at a somewhat higher dosage (5.0 μ c./ml.), followed by mixing for 2 min on a cell suspension mixer, and incubation at 37° C for 1 h immediately preceding termination of the culture. Smears were made of the centrifuged cell deposit. Slides were coated with Eastman 'Kodak NTB 3' emulsion, exposed for 7 days and stained through the fixed emulsion with a modified MacNeal's tetrachrome². At the dosage of tritiated uridine used, distinction between nuclear and cytoplasmic labelling is difficult if the nuclear-cytoplasmic (*N:C*) ratio is high, especially when heavy labelling is present. However, there are two types of transforming lymphocyte equally distributed in these cultures³. They make their appearance in increasing numbers during the first 24 h before any evidence of DNA synthesis occurs³. The first of these types, the transitional lymphocyte, has a very high *N:C* ratio, with a leptochromatic nucleus occupying almost all the cell (Fig. 1*a*), and in this cell it is difficult to be sure whether labelling is cytoplasmic or not. The other type, the so-called atypical transitional lymphocyte (Fig. 1*b*), has a much lower *N:C* ratio, and, in our experience, it is only this cell which really provides suitable material for the investigation of cytoplasmic labelling in its earliest stages.

Immediately after setting up the culture, there was nuclear labelling, but virtually no evidence of cytoplasmic labelling in lymphocytes at 0 h, that is after incubating for 1 h with tritiated uridine (Fig. 2, *a* and *b*). At 3 and 6 h there was a significant increase in the proportion of labelled cells and their mean grain counts, but the labelling was still confined to the nucleus in the overwhelming majority of cells. At 12 h there was weak cytoplasmic labelling, but from 18 h onwards this was more marked (Fig. 3, *a* and *b*), together with further progressive increases

both in the proportion of labelled cells and their mean grain counts.

At 48 h there was also significant cytoplasmic labelling of blast cells after 1 h terminal incubation with uridine-5-³H. Here again blast cells with a high *N:C* ratio were

Fig. 1. 24-h culture. *a*, Transitional lymphocyte with very high *N:C* ratio ($\times 1,500$). *b*, Atypical transitional lymphocyte with medium *N:C* ratio ($\times 1,500$).

Fig. 2. 0-h culture. *a* and *b*, Medium-sized lymphocytes showing nuclear labelling only (³H-uridine added for 1 h—see text) ($\times 1,500$).

Fig. 3. 24-h culture. *a* and *b*, Atypical transitional lymphocytes showing nuclear and cytoplasmic labelling (³H-uridine added for 1 h at term—see text) ($\times 1,500$).

Fig. 4. 48-h culture. *a* and *b*, Blast cells with low *N:C* ratio showing nuclear and cytoplasmic labelling (³H-uridine added for 1 h at term—see text) ($\times 1,500$).

Fig. 5. 48-h culture. *a*, Blast cell showing nuclear labelling only (³H-uridine added immediately prior to the making of smears—see text) ($\times 1,500$). *b*, Blast cell showing nuclear and cytoplasmic labelling. Large atypical transitional lymphocyte (below) showing nuclear labelling only (³H-uridine added for 15 min at term—see text) ($\times 1,500$).

difficult to interpret, but in blast cells with a low $N:C$ ratio³ one invariably found cytoplasmic labelling markedly in excess of background labelling (Fig. 4, *a* and *b*).

In 48-h cultures when smears were made as soon as possible after the addition of uridine-5-³H to the cell suspension without further incubation, nuclear labelling only was observed both in atypical transitionals and blast cells (Fig. 5*a*). The time between the addition of tritiated uridine and preparation of the smear was of the order of 7–8 min. If the suspension was incubated for 7.5 min after the addition of this nucleoside, similar results were obtained, but after incubation for 15 min cytoplasmic labelling was present in some cells, though the number of cells and intensity of labelling were appreciably less than with the usual period of 60 min (Fig. 5*b*).

Harris⁴ has shown that in the nuclei of mammalian cells there are mechanisms both for the degradation of much of the rapidly labelled RNA, and also for the production of a more stable form of this compound. He has suggested that there may be overproduction of the more rapidly labelled RNA, a fraction of which is used to produce more stable RNA and the remainder degraded. Whether this cytoplasmic labelling represents a relatively rapid transfer of the more stable nuclear RNA to cytoplasm, once the process of cell growth initiated by PHA is under way, or whether it represents diffusion of acid-soluble end products outwards from the nucleus⁴ or both, remains uncertain.

We thank Mr. A. K. Sykes for taking the photomicrographs and Mr. C. L. Chen for technical assistance. One of us (G. C. B. W.) thanks the K. G. Laurence Group of Limited Companies for generous supplementary financial assistance.

GENETICS

Differential Deoxyribonucleic Acid Replication in the Giant Foot-pad Cells of *Sarcophaga bullata*

GIANT polytene chromosomes from the salivary glands of various fly larvae have been extensively examined; because of their enormous size they have become one of the most important tools in investigations of gene activity and nuclear-cytoplasmic relationships. Malpighian tubules and certain other tissues of flies also possess polytene chromosomes, but they show a lower degree of polyteny. It is generally accepted that in most animal and plant cells there is a constant relation between the DNA content and the number of chromosome 'sets' it contains. Synthesis of DNA results in a doubling of this pre-existing amount; a dipteran polytene chromosome may result from more than a thousand such replications¹. Recently it has been suggested² that differentiation in a multicellular organism involves the progressive inactivation of DNA, and that, in the polytene chromosome, three conditions characterize these inactivated regions: first, inactivity with respect to RNA synthesis; secondly, late replication, replication being slower and continuing longer than over the rest of the chromosome; thirdly, the appearance of dense packing. Heavy bands and heterochromatic regions are given as typical examples of such regions.

Recently, giant cells containing giant polytene chromosomes have been described for the pupal foot-pads of developing adult flies^{3,4}. Continued work with this

material, particularly with the fly *Sarcophaga bullata*, shows that, whereas the highly polytene condition of the giant chromosomes is reached by DNA replication along the whole chromosome length, as typically occurs in salivary gland chromosomes, there is also seen here striking differential replication of specific chromosomal regions, at specific times, resulting in the 'budding off' of dozens of 'granules', each containing DNA. The granules lie between the chromosomes and the nuclear membrane, most commonly immediately within the nuclear membrane.

Two of these giant cells occur to each foot-pad. In the first-day pupa (reared at 25° C) the cells are little larger than those surrounding tenent hair cells⁴ that have just completed mitosis (cf also Figs. 1*A* and 1*B*). In a two-day pupa the nucleus of the future giant cell is still very small in comparison with the whole developing foot-pad, whereas in a four-day pupa the nucleus is approximately 70 μ in diameter, and the cell itself extends over half (the second cell covers the other half) of the entire dorsal surface of the pad. This extremely rapid growth in a relatively short time is accompanied by correspondingly rapid DNA synthesis resulting in the very highly polytene, distinctly banded chromosomes (Fig. 1*A*). Throughout the growth phase the nucleolus is very large relative to the size of the nucleus, but in the mature cell the greater growth of the chromosomes results in a proportionately smaller nucleolus. It contains strands of DNA, but these occur in the core of the nucleolus and do not extend to, and beyond, the periphery (Fig. 2*E*). The DNA granules are not associated with the nucleolus. A micro-nucleolus is also present in the growing cells (located at the position *X* on chromosome *B* Fig. 1). It is not present in this day-7 preparation, as it disappears in a late day-4 pupa, by which time growth has ceased. Characteristic puffing occurs in the chromosomes during growth and at the same time as DNA replication. These puffs are very probably involved in the growth processes. However, it is immediately before and during the extensive secretion and the darkening of the adult cuticle that the most striking changes in the puffing sequences occur. Fig. 2*A* is of a whole nucleus contained within the foot of a ten-day pupa in which darkening of the cuticle is proceeding. The two puffs seen on the nucleolus-bearing chromosome (*A'*, Fig. 1—at arrows—does not have these puffs in the day-7 pupa) characteristically appear only at this time of cuticle darkening. A very large puff is also present (slightly out of the plane of focus) at the third arrow. This also is characteristically large at this stage of development (puffs are present along this chromosome: *C'*, Fig. 1, but at day 7 the very large puff is not present).

Such chromosomal RNA puffs are much-studied features of dipteran salivary gland chromosomes. DNA puffs, on the other hand, are recorded from relatively few forms, for example, in the sciarids, *Rhynchosciara* and *Sciara coprophila*⁵, and in the chironomid *Glyptotendipes*⁶. In these cuticle-secreting cells of *Sarcophaga*, the shorter arm of the nucleolus bearing chromosome (Fig. 1: *A'*) possesses a very characteristic DNA puff. Throughout the time of cuticle secretion this has a highly granular appearance, but is most noticeably puffed in a day 7–8 pupa (Fig. 2*C*).

The chromosomes in the fully grown cell, such as that shown in Fig. 2*A*, are aligned, very strikingly, immediately within the nuclear membrane. They present a beautiful appearance, being so arranged that at no point do two chromosomes or two chromosome regions overlap, with the result that each and every chromosome band lies at right angles and close to the nuclear membrane. They are connected to the nuclear membrane by numerous strands, clearly seen in isolated nuclei, gently rolled between slide and coverslip and viewed with phase optics (similar attachment to the nuclear membrane has been described for the salivary gland of *Chironomus dorsalis* by Kimoto⁷).

At all stages of cuticle secretion and darkening the DNA granules are present, and their distribution can be determined even in whole nuclei. Particular groups of granules arise from the chromosomes at specific developmental stages. At these times the size and appearance of the granules are similar to those of the granules of the chromosomal region from which they appear to be 'budding off'. The granules maintain contact with one another, with the chromosomes, and with the nuclear membrane, by strands which can be seen with RNA staining procedures. They do not appear to be connected by DNA strands, although these could be present, but beyond the resolution of the light microscope. The granules show up with equal clarity in Feulgen/fast green preparations, in azure B at pH 4, in orcein/light green, and in methyl green/pyronin preparations; they are digested with DNase. Each granule is surrounded by a peripheral region the staining reaction of which is similar to that of the many conspicuous chromosomal RNA puffs. In many instances the region of the chromosome from which the granules arise is unexpanded; in others, the regions of the centromeres are involved. The DNA puff on the nucleolus-bearing chromosome is also suspected of having given rise to granules which have been found to lie between it and the nuclear membrane, as is seen in Fig. 2D. Likewise a puff occurring near the end of the longer arm of the longest chromosome (E'', Fig. 1), in a stage 3-4 pupa, appears as a DNA puff, and at this stage numerous granules are in close proximity, so that it, too, is suspected of being involved in the replication of DNA granules.

This puff, in Fig. 1 (arrow), which is of a later day-7 pupa, has resumed a normal banded appearance.

The DNA granules are of relatively large dimension. For comparison of size, Figs. 1A and B show a group of about five granules at the lower left of A which approach the overall dimensions of the whole chromosomes of B. The invariable presence of the granules, their origin at different times and their location immediately within the nuclear membrane tend to suggest that they are performing some function vital to the cell's activity. That such granules are present in these cells and not apparently in the better-known salivary gland cells may find an explanation in some developmental differences. Whereas a salivary gland cell grows slowly and takes several instars to attain maximum size, growth here is extremely rapid, and increase in size is tremendous. Furthermore, the cell is called into action to produce cuticle when seemingly immediately cell growth has ceased. Also, the volume of secretion is large and produced at a rapid rate, which presumably means that turnover must be rapid. It would seem that the ribosomal elements involved in the formation of mucoproteins and other cuticular elements are required in very large numbers within a short time-span. It is not impossible that these extra-chromosomal DNA granules may be performing the function of 'sub-factories' (of the specific gene loci from which they have arisen) for the production of messenger RNA, a need which may not otherwise be met, even by the extensive DNA replication resulting in the high degree of polyteny attained along the rest of the chromosome complement.

Fig. 1. A, Chromosome squash of giant foot-pad cell nucleus from a day-7 pupa of *Sarcophaga bullata*, reared at 25° C. ch, Chromocentre; g, DNA granules; N, nucleolus; X, position of micro-nucleolus at earlier stage. Arrows: position of puffs referred to in text. A' A'', B' B'', C' C'', D' D'', E' E'': ends of short and long arms respectively of chromosomes. Stained: orcein/light green. B, Metaphase chromosome squash from testis of *Sarcophaga* for comparison of chromosome size with A. Lacto-acetic-orcein squash

Fig. 2. A, Whole nucleus from a day-10 pupa of *Sarcophaga*, Feulgen stained. The chromosomes are aligned immediately within the nuclear membrane, and this micrograph is focused on those chromosomes lining the upper border of the spherical nucleus. Note the DNA granules at the shorter arrows, and the chromosomal puffs at the longer arrows (referred to more specifically in text). B, C, Two views of the shorter arm of the nucleolus-bearing chromosome. In B the region at the single arrow is granular, but not puffed; day-5 pupa. In C the same region is distinctly puffed; day-8 pupa. Feulgen/fast green. D, Chromosome squash of a day-8 foot showing granules of DNA lining the inner border of the nuclear membrane (top left), and near the DNA puff on the shorter arm of the nucleolus bearing chromosome. Feulgen/fast green, lightly squashed. E, Lacto-acetic-orcein squash to show the distribution of DNA within the nucleolus; focus is on the nucleolus and not the chromosome.

It has been suggested² that the presence of early and late replicating DNA along the same polytene chromosome is "indicative of the presence of multiple sub-units arranged tandemly in the metazoan chromosomes". The present example of DNA synthesis at specific locations would lend additional support to this suggestion. Here, however, it would seem that it is not only a question of late or early replication but of repeated 'extra' replication occurring at certain regions along the chromosomes. Since the number, position of origin, and hence the composition of these particular granules is likely to be specific to these cells, they would seem, at first sight, to be visible evidence of seemingly irreversible nuclear differentiation.

The exact function of these granules in relation to other chromosomal activities, such as that of the nucleolus, of the micro-nucleolus, of the DNA puffs and of the complex sequences of RNA puffs, pose some new and intriguing questions. Kaufman and Gay⁶ described, at the electron microscope level, 'extra chromosomal' material, associated with the phenomenon of nuclear-membrane 'blebbing', in *Drosophila*. Gay also described⁹ DNA as 'secreted' by certain bands of the late third instar salivary gland chromosome of *Drosophila*. Extra-chromosomal DNA has

also been described by Beyreuther¹⁰ during oogenesis in Tipulidae, where it is produced from heterochromatic regions of the chromosomes. These observations and the findings recorded here may be of comparable phenomena; the very considerable size and large numbers of the present granules make the foot-pads particularly suited for further investigation at both light- and electron-microscope levels. Work is continuing using histochemical, autoradiographic and electron-microscope techniques. Details of the general development of the feet, of the banding pattern of each of the chromosomes, and the striking puffing sequences at the various developmental stages are being given elsewhere.

This work has been supported by a grant from the National Science Foundation.

PSYCHOLOGY

Behavioural Deficit in the Rat induced by feeding Phenylalanine

PHENYLKETONURIA, high serum levels of phenylalanine and its metabolites, and elevated levels of free phenylalanine in the milk can be induced in pregnant and lactating animals by the addition of phenylalanine to the diet¹. The effects on the learned behaviour of offspring born and raised by mothers on such diets are of interest because the rate of incorporation of phenylalanine into brain tissue is higher before weaning than later^{2,3}. High levels of phenylalanine produce behavioural impairment in mice only if fed prior to weaning⁴. Furthermore, inability to metabolize phenylalanine normally may have no effect on the intelligence of human phenylketonurics if dietary treatment allows early normal mental development⁵. High levels of phenylalanine may produce behavioural impairment only when present during an early critical period of development.

This report describes a behavioural deficit due to adding 7 per cent D,L-phenylalanine (Phe) to the maternal diet of rats prior to weaning of their pups. In addition, we report evidence suggesting partial attenuation of the observed deficit by maintenance on normal diets after weaning.

Seven pregnant Holtzman rats were placed on special diets 2 days before parturition. A basal diet of Rockland ground mouse chow contained 7 per cent Phe for four of these; the basal diet for the remainder contained 7 per cent 'CellufLOUR' (C). Live pups were born to all mothers. The pups were left with their mothers until weaning at the age of 21 days. Seventeen pups from litters of the mothers on C and seventeen pups from the litters of the mothers on Phe had survived. After weaning, nine randomly chosen pups from each group of seventeen were fed the Phe diet and eight from each group were fed the C diet. Three pups from the maternal Phe group that had been placed on post-weaning C diet died prior to behavioural testing.

At 10 weeks of age all pups, after 24 h of water deprivation, were trained in an LVE 1316 operant behaviour chamber (Lehigh Valley Electronics) to approach a dipper to obtain a drop of water. Afterwards, they were deprived

of water once each week for the 24 h preceding behavioural testing in the chamber.

During a second 1-h session, each pup was trained to depress a small lever in order to obtain each drop of water. During the third session only the first five responses were reinforced with water, and all subsequent responses during 1 h were unreinforced. After this exposure to extinction, all pups were given three weekly 0.5-h sessions of retraining during which every lever press was reinforced. No experimental differences between groups were evident during these six lever-pressing sessions. All pups learned, extinguished, and relearned quite rapidly.

During sessions 7-28 (16-37 weeks of age) responses were reinforced on a DRL (Differential Reinforcement of Low rate of responding) 12-sec schedule⁶. Only responses that occurred after a 12-sec period of non-responding were reinforced. Responses that followed a pause of less than 12 sec were not reinforced. Twenty reinforcements were obtained during each DRL session.

Group differences were immediately apparent on the DRL schedule, and persisted throughout the 5-month test, as shown in Fig. 1 (ref. 7). Pups with pre- and post-weaning Phe (group Phe-Phe) made significantly (all probability values reported are based on two-tailed 'U' tests) more responses ($P < 0.001$) than pups fed Phe only after weaning (group C-Phe). Pups fed pre-weaning Phe and post-weaning C (group Phe-C) made significantly more responses ($P < 0.05$) than pups with pre- and post-weaning C (groups C-C). Thus, in both comparisons, pre-weaning Phe increased responding in adulthood.

There was very little overlap between the response-levels of pups from the two pre-weaning conditions. Only four pups from C-diet mothers had mean responses per session higher than the lowest mean of any pup from Phe mothers. The observed differences were therefore not due to a selective effect of different mortality rates of the two

groups. If the groups were actually the same, and if mortality had selectively eliminated pups that would have shown high or low response levels, the range of one remaining group of subjects would have subtended that of the other. The response levels of a majority of pups from Phe mothers were consistently higher than those of any pups from C mothers.

The adult behaviour of both groups of pups from Phe mothers was less efficient than that of those from C mothers. Pre-weaning pups made many more unnecessary responses than pre-weaning C pups and thus prolonged the amount of time it took to obtain their reinforcements ($P < 0.001$). This inefficiency persisted during adulthood.

Initiation of post-weaning Phe had no significant effect on pups which had previously had pre-weaning C diet (group C-Phe versus group C-C). However, the opposite shift in diet tended to have an effect; pups in group Phe-Phe made more responses than those in group Phe-C ($P < 0.06$). Post-weaning dietary treatment with Phe affected pups that already had a behavioural deficit due to pre-weaning Phe; but it had no effect on those with pre-weaning C diets. Two interpretations of these results are possible: initiation of post-weaning C diet may have produced a partial attenuation of the pre-weaning deficit; or continuance of the Phe diet could have made worse the deficit already started.

One major problem in interpreting our data concerns the question of whether the adult deficit was due to a change in metabolism or to other factors. For example, if Phe mothers behaved differently toward their pups than did C mothers, this differential behaviour could have caused adult behavioural differences in offspring not attributable to Phe metabolism. Conclusive evidence bearing on this problem will require further research.

The interaction of pre- and post-weaning dietary effects on the deficit, however, tends to favour a metabolic interpretation of its cause. With our behavioural test, a deficit due to post-weaning Phe was apparent only after a history of pre-weaning Phe.

If one were to assume that the cause of the deficit was indeed metabolic, a second problem of interpretation would concern the nature of this deficit. Was it due to changes in learning ability, motivation, sensory capacity, simple debilitation, or to still other factors?

The higher response-levels observed during DRL testing weigh against the likelihood that the deficit was one of gross debilitation or of lack of motivation. On the other hand, the higher response-levels could have been due to heightened motivation or increased motor activity; we did not, however, note any apparent changes in level of activity or amount of water consumed by the different groups.

Clearly, further research is necessary to distinguish between the remaining interpretations in order to establish whether or not the performance deficit is, in fact, due to impaired learning ability.

This investigation was supported in part by Public Health Service research grant MH 7663 from the National Institutes of Health.

Fig. 1. Mean cumulative lever-pressing responses emitted by four groups of water-deprived rats. Only responses that occurred after a 12-sec period of non-responding were reinforced. High response levels indicate inefficient behaviour. Young rats from mothers fed a basal diet of Rockland mouse diet containing 7 per cent D,L-phenylalanine or containing 7 per cent 'Cellufloor' were used. After weaning the group previously fed phenylalanine was divided into two sub-groups; nine pups were continued on 7 per cent D,L-phenylalanine (Phe-Phe) and the diet of five pups was changed to 7 per cent 'Cellufloor' (Phe-C). After weaning the group previously fed 'Cellufloor' was also divided into two groups; the diet of nine pups was changed to 7 per cent D,L-phenylalanine (C-Phe) and eight pups were continued on 7 per cent 'Cellufloor' (C-C).

FORTHCOMING EVENTS

(Meetings marked with an asterisk are open to the public)

Monday, December 6

UNIVERSITY OF LONDON (at the Postgraduate Medical School of London, Du Cane Road, London, W.12), at 4 p.m.—Dr. J. C. Gilsen: "Asbestos, Recent Work on the Biological Importance of Fibre Type".*

INSTITUTION OF ELECTRICAL ENGINEERS, ELECTRONICS DIVISION (at Savoy Place, London, W.C.2), at 5.30 p.m.—Discussion on "Acoustic-Wave Amplification" opened by Dr. E. G. S. Paige and Mr. C. P. Sandbank.

INSTITUTION OF MECHANICAL ENGINEERS, THERMODYNAMICS AND FLUID MECHANICS GROUP (at 1 Birdcage Walk, Westminster, London, S.W.1), at 6 p.m.—Discussion on "Is Heat Transfer Theory of Any Use?"

ROYAL GEOGRAPHICAL SOCIETY (at 1 Kensington Gore, London, S.W.7), at 6 p.m.—"The Underwater Search" (Colour Film).

SOCIETY OF CHEMICAL INDUSTRY, LONDON SECTION (joint meeting with the Heavy Organic Chemicals Group, at 14 Belgrave Square, London, S.W.1), at 6.30 p.m.—Dr. H. L. Riley: "Recent Developments in the Tonnage Production of Aromatic Chemicals".

Tuesday, December 7

UNIVERSITY OF LONDON (at the Westminster Medical School, Horseferry Road, London, S.W.1), at 5.15 p.m.—Dr. J. F. Zilva: "Physiological Variations in Serum Iron Levels".*

INSTITUTION OF ELECTRICAL ENGINEERS, CONTROL AND AUTOMATION DIVISION (at Savoy Place, London, W.C.2), at 5.30 p.m.—Discussion on "Human Factors in the Control of Road Vehicles", opened by Mr. I. D. Brown and Mr. R. L. Moore.

UNIVERSITY OF LONDON (at Imperial College of Science and Technology, London, S.W.7), at 5.30 p.m.—Prof. H. R. Hower: "The Length and Breadth of Zoology" (Inaugural Lecture).*

UNIVERSITY OF LONDON (at the London School of Hygiene and Tropical Medicine, Keppel Street, Gower Street, London, W.C.1), at 5.30 p.m.—Dr. P. J. Lachmann: "Allergic Reactions, Connective Tissue and Disease". (Twelfth of fifteen lectures on "The Scientific Basis of Medicine" organized by the British Postgraduate Medical Federation).*

INSTITUTION OF MECHANICAL ENGINEERS, LUBRICATION AND WEAR GROUP (at 1 Birdcage Walk, Westminster, London, S.W.1), at 6 p.m.—Discussion on "Compressor Fires and Explosions".

PLASTICS INSTITUTE, LONDON SECTION (at the Wellcome Building, Euston Road, London, N.W.1), at 6.30 p.m.—Dr. H. Ebneth (Farbenfabriken Bayer AG): "A General Survey of ABS Materials".

Wednesday, December 8

UNIVERSITY OF LONDON (at the Postgraduate Medical School of London, Du Cane Road, London, W.12), at 2 p.m.—Dr. F. C. Greenwood: "Assay of Protein Hormones".*

INSTITUTE OF NAVIGATION (at the Royal Institution of Naval Architects, 10 Upper Belgrave Street, London, S.W.1), at 3 p.m.—Meeting on "The Training of Navigators".

SIR THOMAS MIDDLETON MEMORIAL TRUST (in the Auditorium, The Wellcome Building, 183 Euston Road, London, N.W.1), at 3 p.m.—Dr. J. L. Monteith: "Physical Limitations to Crop Growth" (Tenth Memorial Lecture).

INSTITUTION OF ELECTRICAL ENGINEERS, CONTROL AND AUTOMATION DIVISION (at Savoy Place, London, W.C.2), at 5.30 p.m.—Mr. P. L. Moreton: "Simple New Power-Factor Meter Utilizing Dry Reed Relays"; Mr. J. Dean and Mr. C. E. Lyth: "A Wattmetric Transducer".

UNIVERSITY OF LONDON (in the Anatomy Theatre, University College, Gower Street, London, W.C.1), at 5.30 p.m.—Dr. J. Kutina (Charles University, Prague): "Genetic Interpretation of Zoning Phenomena in Ore Deposits".*

ENVIRONMENTAL GROUP (in the Department of Electrical Engineering, Imperial College of Science and Technology, London, S.W.7), at 6 p.m.—Discussion Meeting on "Information for Architects on Environmental Matters".

INSTITUTION OF ELECTRICAL ENGINEERS, ELECTRONICS DIVISION (at Savoy Place, London, W.C.2), at 6 p.m.—Discussion on "A Review of the Present Situation of Electronic Switching", opened by Mr. J. A. Lawrence and Mr. J. R. Pollard.

INSTITUTION OF ELECTRONIC AND RADIO ENGINEERS, TELEVISION GROUP (at the London School of Hygiene and Tropical Medicine, Keppel Street, Gower Street, London, W.C.1), at 6 p.m.—Symposium on "Semi-conductor Scanning Circuits".

ROYAL INSTITUTE OF CHEMISTRY, LONDON SECTION (at Shell-Mex House, Strand, London, W.C.2), at 6 p.m.—Annual General Meeting, followed by Dr. R. E. Parker: "The Work of the R.I.C.".*

SOCIETY OF INSTRUMENT TECHNOLOGY (at Manson House, 26 Portland Place, London, W.1), at 6 p.m.—Mr. E. Duncombe: "Some Transducer Techniques for Use at Elevated Temperatures".

INSTITUTE OF INFORMATION SCIENTISTS (at the Whitehall Hotel, Bloomsbury Square, London, W.C.1), at 6.15 p.m.—Mr. F. Liebesny: "Information from Patents".

INSTITUTION OF CIVIL ENGINEERS (at Great George Street, Westminster, London, S.W.1), at 6.15 p.m.—Mr. D. G. McBeth: "The Victoria Line Survey".

SOCIETY OF CHEMICAL INDUSTRY FOOD GROUP—NUTRITION PANEL (at 14 Belgrave Square, London, S.W.1), at 6.15 p.m.—Mr. A. B. E. De Jong: "Survival Rations".

INSTITUTE OF SCIENCE TECHNOLOGY, LONDON BRANCH (at King's College, Strand, London, W.C.2), at 6.30 p.m.—Mr. S. Lenton: "Brazilian Adventure".

OIL AND COLOUR CHEMISTS' ASSOCIATION, LONDON SECTION (in the Small Physics Lecture Theatre, Imperial College of Science and Technology, London, S.W.7), at 7 p.m.—Mr. T. B. M. Rybak: "The Use of Computers in Process Control".

ROYAL INSTITUTE OF CHEMISTRY, LONDON SECTION (at Hatfield College of Technology, Roe Green, Hatfield), at 7 p.m.—Dr. A. E. A. Werner: "The Scientific Examination of Paintings and Antiquities" (Ladies' Evening).

ASSOCIATION OF THE WILLIAM PENGELLAY CAVE RESEARCH CENTRE, WITH IMPERIAL COLLEGE CATING CLUB (in the Department of Physics, Imperial College of Science and Technology, Prince Consort Road, London, S.W.7), at 7.30 p.m.—Dr. Harold Lord: "Cave Communications".

Thursday, December 9

INSTITUTION OF MECHANICAL ENGINEERS, MANIPULATIVE AND MECHANICAL HANDLING MACHINERY GROUP (at 1 Birdcage Walk, Westminster, London, S.W.1), at 4.30 p.m.—Discussion on "Bulk Handling and Storage of Iron Ore and Coal".

ROYAL SOCIETY (at Burlington House, Piccadilly, London, W.1), at 4.30 p.m.—Dr. W. Hayes, F.R.S.: "Some Controversial Aspects of Bacterial Sexuality" (The Leeuwenhoek Lecture).

INSTITUTE OF PETROLEUM, ECONOMICS AND OPERATIONS GROUP (at 6 New Cavendish Street, London, W.1), at 5.30 p.m.—Mr. Bal Wagle: "Some Recent Developments in Forecasting Techniques".

INSTITUTION OF CIVIL ENGINEERS, TRANSPORTATION ENGINEERING GROUP (at Great George Street, Westminster, London, S.W.1), at 5.30 p.m.—Mr. D. B. Sampson: "Public Relations and Its Effect on Traffic Behaviour in North America".

INSTITUTION OF ELECTRICAL ENGINEERS, ELECTRONICS DIVISION (at Savoy Place, London, W.C.2), at 5.30 p.m.—Dr. D. E. N. Davies and Dr. B. S. McCartney: "Cylindrical Arrays with Electronic Beam Scanning"; Dr. D. E. N. Davies: "Beam-Positioning Radar Systems Utilizing Continuous Scanning Techniques".

INSTITUTION OF ELECTRICAL ENGINEERS, POWER DIVISION (at Savoy Place, London, W.C.2), at 5.30 p.m.—Prof. G. H. Rawcliffe and Dr. W. Fong: "Two-speed Induction Motors Using Fractional-Slot Windings"; Dr. W. Fong: "Wide-ratio Two-speed-Single-winding Induction Motors".

UNIVERSITY OF LONDON (at the London School of Hygiene and Tropical Medicine, Keppel Street, Gower Street, London, W.C.1), at 5.30 p.m.—Prof. F. T. G. Prunty: "Androgen Metabolism in Man—Some Current Concepts". (Thirteenth of fifteen lectures on "The Scientific Basis of Medicine" organized by the British Postgraduate Medical Federation).*

UNIVERSITY OF LONDON (in the Anatomy Theatre, University College, Gower Street, London, W.C.1), at 5.30 p.m.—Dr. J. Kutina (Charles University, Prague): "Selection Replacement in Hypogene Ore Deposition".*

SOCIETY FOR ANALYTICAL CHEMISTRY, BIOLOGICAL METHODS GROUP (at "The Feathers", Tudor Street, London, E.C.4), at 6.30 p.m.—Annual General Meeting, followed by a Discussion Meeting on "Problems and Dilemmas in Microbiological Assay" opened by Mr. S. A. Price.

ROYAL SOCIETY OF TROPICAL MEDICINE AND HYGIENE (at Manson House, 26 Portland Place, London, W.1), at 7.30 p.m.—Dr. Cicely Williams: "Population Problems in Developing Countries".

Friday, December 10

UNIVERSITY OF LONDON (at the Institute of Obstetrics and Gynaecology, Queen Charlotte's Hospital, London, W.6), at 11.15 a.m.—Mr. C. J. Dewhurst: "The Determination of Sex".

INSTITUTION OF ELECTRICAL ENGINEERS, CONTROL AND AUTOMATION DIVISION (at Savoy Place, London, W.C.2), at 5.30 p.m.—Discussion on "The ONC: Better Opportunities for Failure?" opened by Mr. E. Toner.

SOCIETY FOR ANALYTICAL CHEMISTRY, MICROCHEMICAL METHODS GROUP (at the Chemical Society, Burlington House, Piccadilly, London, W.1), at 6.45 p.m.—Annual General Meeting, followed by Mr. A. K. Soper: "Practical Experience in Statistics Applied to Chemistry".

Saturday, December 11

INNER LONDON EDUCATION AUTHORITY (at the Horniman Museum, London Road, Forest Hill, London, S.E.23), at 3.30 p.m.—Dr. John Waechter: "Underwater Archaeology".*

Monday, December 13

OPERATIONAL RESEARCH SOCIETY (at the Royal Aeronautical Society, 4 Hamilton Place, London, W.1), at 4.30 p.m.—Mr. D. W. Trigg: "Logic of Stock Replenishment Subject to Production Constraints".

SOCIETY OF CHEMICAL INDUSTRY, COLLOID AND SURFACE CHEMISTRY GROUP (at 14 Belgrave Square, London, S.W.1), at 5.30 p.m.—Mr. S. A. Mitchell: "The Surface Properties of Amorphous Silicas".

INSTITUTION OF ELECTRONIC AND RADIO ENGINEERS (at 9 Bedford Square, London, W.C.1), at 6 p.m.—Annual General Meeting.

INSTITUTION OF MECHANICAL ENGINEERS, HYDRAULIC PLANT AND MACHINERY GROUP (at 1 Birdcage Walk, Westminster, London, S.W.1), at 6 p.m.—Discussion on "Application of Control Theory to Control of Surges".

INSTITUTION OF ELECTRICAL ENGINEERS, LONDON GRADUATE AND STUDENT SECTION (at Savoy Place, London, W.C.2), at 6.30 p.m.—Mr. L. Drucquer—Presidential Address.

ROYAL GEOGRAPHICAL SOCIETY (at 1 Kensington Gore, London, S.W.7), at 8.15 p.m.—Dr. R. B. Sarjeant: "Background to the Yemen War".

APPOINTMENTS VACANT

APPLICATIONS are invited for the following appointments on or before the dates mentioned:

LECTURER (with qualifications and research interests preferably in some branch of mathematical statistics, but candidates with interests in applied statistics will also receive consideration) IN THE DEPARTMENT OF PURE MATHEMATICS AND MATHEMATICAL STATISTICS—The Registrar, University College of South Wales and Monmouthshire, Cathays Park, Cardiff (December 10).

RESEARCH ASSISTANT (graduate in physiology, biochemistry or medicine) IN THE PHYSIOLOGY DEPARTMENT (current research is on pituitary tissue culture, and on the reaction between the pituitary and cancer)—The Professor of Physiology, University College, Galway, Republic of Ireland (December 10).

ASSISTANT LIBRARIAN (qualified librarian, preferably with some experience in a college library)—The Clerk to the Governors, Woolwich Polytechnic, Wellington Street, London, S.E.18 (December 13).

LECTURER IN THE DEPARTMENT OF PURE MATHEMATICS or the DEPARTMENT OF STATISTICS, School of Mathematics, University of New South Wales—The Association of Commonwealth Universities (Branch Office), Marlborough House, Pall Mall, London, S.W.1 (Australia and London, December 15).

SENIOR LECTURER/LECTURER IN PURE MATHEMATICS at the University of New South Wales, Australia—The Association of Commonwealth Universities (Branch Office), Marlborough House, Pall Mall, London, S.W.1 (Australia and London, December 15).

COMPUTER MANAGER (with previous experience with large-scale electronic computers) for the KDF 9 installation in the Electronic Computing Laboratory—The Registrar, The University, Leeds, 2 (December 17).

CHAIR OF MICROBIOLOGY—The Secretary of the University Court, University of Glasgow, Glasgow (December 18).

LECTURER IN ECOLOGY IN THE DEPARTMENT OF ZOOLOGY—The Registrar, University of Leicester, Leicester (December 18).

LECTURERS (2) IN APPLIED MATHEMATICS—The Registrar, University of Leicester, Leicester (December 18).

PROFESSOR AND HEAD (with an appropriate combination of academic research and industrial experience) of the DEPARTMENT OF MATERIALS SCIENCE AND TECHNOLOGY—The Principal, Brunel College, Woodlands Avenue, London, W.3 (December 20).

CHAIR OF ELECTRICAL ENGINEERING SCIENCE—The Registrar, University of Essex, Wivenhoe Park, Colchester, Essex (December 21).

SECOND CHAIR OF ZOOLOGY AT QUEEN MARY COLLEGE—The Academic Registrar, University of London, Senate House, London, W.C.1 (December 22).

CHAIR OF BIOCHEMISTRY AND AGRICULTURAL BIOCHEMISTRY—The Registrar, University College of Wales, Aberystwyth (December 31).

LECTURER IN ORGANIC CHEMISTRY—The Secretary, The Queen's University, Belfast, Northern Ireland (December 31).

PROFESSOR IN EDUCATION at the School of Education—The Registrar, The Chinese University of Hong Kong, Hang Seng Bank Building, 677 Nathan Road, Kowloon, Hong Kong (December 31).

SENIOR LECTURER or LECTURER IN BOTANY; and a SENIOR LECTURER or LECTURER IN ZOOLOGY at the University of Natal, South Africa—The Association of Commonwealth Universities (Branch Office), Marlborough House, Pall Mall, London, S.W.1 (South Africa and London, December 31).

SENIOR LECTURER or LECTURER (preferably with qualifications in one of the following fields: topology, applied mathematics or algebra) IN THE DEPARTMENT OF MATHEMATICS, University of Ghana—The Assistant Registrar, Ghana High Commission, Higher Education Section, 15 Gordon Square, London, W.C.1; or The Registrar, University of Ghana, P.O. Box 25, Legon, Accra, Ghana (December 31).

SENIOR LECTURER or LECTURER (with special qualifications and interests in economic geography) IN GEOGRAPHY—The Secretary, The Queen's University, Belfast, Northern Ireland (December 31).

SENIOR SCIENTIFIC OFFICER/SCIENTIFIC OFFICER-CHEMIST (experienced in water chemistry and preferably a knowledge of the chemistry of submerged soils)—The Director, Tropical Fish Culture Research Institute, Batu Berendam, Malacca, Malaysia (December 31).

TEMPORARY LECTURER IN ELECTRICAL ENGINEERING at the University of Western Australia—The Association of Commonwealth Universities (Branch Office), Marlborough House, Pall Mall, London, S.W.1 (Australia and London, January 8).

CHAIR OF PHYSICAL CHEMISTRY—The Secretary, The Queen's University, Belfast, Northern Ireland (January 15).

SENIOR LECTURER (with suitable academic qualifications in physics or electronics and preferably experience in university teaching) IN ELECTRONIC PHYSICS IN THE DEPARTMENT OF ELECTRICAL ENGINEERING, Faculty of Applied Science—The Secretary, University of St. Andrews, Queen's College, Dundee, Scotland (January 15).

SENIOR LECTURER IN PHYSICAL OCEANOGRAPHY at the University of Cape Town—The Secretary-General, Association of Commonwealth Universities (Branch Office), Marlborough House, Pall Mall, London, S.W.1; and The Registrar, University of Cape Town, Private Bag, Rondebosch, Cape Town, South Africa (January 31).

CHAIR OF APPLIED GEOLOGY IN THE DEPARTMENT OF MINING ENGINEERING—The Registrar, University of Strathclyde, George Street, Glasgow, G.1.

LECTURER (with experience in experimental research with special reference to learning theory, and in teaching at degree level) IN PSYCHOLOGY—The Registrar, Hatfield College of Technology, Hatfield, Herts.

PROFESSOR and an ASSOCIATE PROFESSOR IN APPLIED MATHEMATICS—The Senior Professor, Applied Mathematics, University of Western Ontario, London, Ontario, Canada.

RESEARCH ASSISTANT (preferably with previous experience in electrophysiological techniques) IN ELECTROPHYSIOLOGY IN THE DEPARTMENT OF ZOOLOGY, to join a small group working on the trophic properties of the insect neuromuscular system—The Secretary of the University Court, University of Glasgow, Glasgow, W.2.

SENIOR GEOLOGIST (male, with a first- or upper second-class honours degree in geology, and at least three years' post-graduate experience in igneous and/or metamorphic rocks, structural geology and prospecting, as well as training in economic geology) IN BRITISH GUIANA, to organize a team of geologists for geological mapping and prospecting and in the investigation of mineral deposits—The Appointments Officer, Ministry of Overseas Development, Room 301, Eland House, Stag Place, London, S.W.1, quoting Ref. RO 218/25/05.

Gas Chromatograph Test Set & Reference Signal Source

enables the Chemist or Instrument Engineer to check quickly the operation and performance of his complete Gas Chromatograph equipment. If the equipment is not operating correctly, it will quickly localise the faulty section. No electrical knowledge is necessary to use this Test Set, which is suitable for Flame Ionisation, Thermistor type and Katharometer Gas Chromatographs.

UNION INVERTED MICROSCOPES FOR BIOLOGICAL APPLICATIONS

- Good quality optics at a low price.
- Long working distance condenser to accommodate thick containers.
- Long working distance 40x phase objective for observation through thick bottomed containers.
- Uses 35 mm. roll or polaroid, retaining binocular whilst photographing.
- Transformer built-in to base.

Full details of this and other UNION microscopes available from:

Finchley, London, N.3.
Telephone: VIRginia 9241.

THE CASE FOR APPLIED RESEARCH

MR. J. C. DANCY, in his presidential address to Section L (Education) of the British Association for the Advancement of Science at its meeting in Cambridge on September 2, discussed the place of technology in a liberal education. This was, in fact, the main theme of the Section's programme, which sought to explore the implications, more particularly for education, of the idea that, instead of the two cultures made familiar by C. P. Snow (now Lord Snow), there is a single unified twentieth-century culture of which technology is an integral part. The programme, moreover, sought to show that many aspects of technology have important educational values and should be studied in their own right, apart from such important considerations as the need for more technologists. To some extent the programme overlapped with discussions in Section X, particularly in so far as the relation between the creative process as understood by the artist, the engineer and the scientist was concerned, or the measures which could be taken to give the technologist a more liberal education.

Mr. A. Koestler addressed himself to the former question in a lecture, "Science—the Dominant Philosophy", to Section X, as did, to some extent, Dr. Magnus Pyke in his presidential address, "Scientific Understanding and the Chief End of Man", while the latter question was discussed by Mr. A. C. D. Peterson and Mr. F. Metcalfe in their contributions to a joint session of the two Sections on "The Cultured Technologist". Despite an aim that was essentially pragmatic, the programme entered into the philosophical, as well as the psychological, aspects to a considerable extent. Nor is this surprising, in view of the extent to which the several addresses also reflected other recent discussions of the broad theme. Both Sir Edward Boyle and Mr. Dancy quoted Sir Peter Medawar's Tizard Memorial Lecture, and the former and Mr. A. Koestler referred at length to Prof. T. S. Kuhn's *The Structure of Scientific Revolutions*.

The Master of Marlborough College argued that technology had a true and proper place as an integral part of a liberal education at the secondary level, and he had in mind, above all, the experience at school of making things which work—the direct and active experience of creative technology. Mr. Dancy maintained that at any level technology required a three-fold creative activity: of intellect, of hand and of eye. Accordingly, it required the skills of the scientist, the artist and the craftsman, and he suggested that the opportunities for creative intellectual work are probably greater to-day in applied than in pure science. He thought that the Nuffield Science Project would help to restore this critical and creative element to science in the schools, but he also emphasized that the technologist was inevitably immersed in human problems, and he suggested that we might find in the arts sixth forms some who would help to make up the present shortage of engineers and technologists.

When, on the following day, Dr. D. G. Christopherson looked at education, he began with a warning that pro-

jects designed to give sixth-formers some insight into the intellectual approach and activity of the technologist should beware of transferring to the schools work which was really the responsibility of the universities and colleges of technology. A good general education was absolutely essential for the technologist, and it would be highly undesirable to disturb the present balance in the sixth-form programmes, which are really much closer to the ideal specifications of departments of engineering and applied science than they are to the contemporary view of those of science and mathematics. He was more disturbed at the tendency of young people to turn away from science as a whole than at the failure to attract a sufficient proportion of the ablest to technology, and he noted the very marked trend for universities to accept a lower standard of entry from their science candidates than from their arts candidates.

Here Dr. Christopherson touched more generally on a point which Prof. R. F. Jones elaborated earlier in the year, with reference to physicists, in his Joseph Payne Memorial Lecture, "The Advancement of Learning, A.D. 1605–2005" (*Nature*, 206, 129; 1965). Like Prof. Jones, he referred to the failure to recruit science teachers of adequate quality in the schools, to which he attributes the trend against science in the sixth form. The task at hand is thus to give science as a whole more immediate impact, interest and relevance to ordinary experience, especially in the middle school, before the choice is made. It is also a matter of helping all young people to feel at home on unfamiliar ground, in a society which is bound to be shaped largely by technology. Dr. Christopherson reminds us that technology cannot function as a closed shop: it works only in a society in which a basic understanding of how it works is widespread.

The intellectual approach of the technologist, he points out, is essentially pragmatic—a characteristic which he shares more thoroughly with the pure scientist than is often realized. This approach is essentially exploratory and experimental, and the thinking required is almost always basically quantitative. Any technological advance involves an element of the creative, and in each of these characteristic attitudes of mind there is an element which is active rather than reflective. Any project to interest and stimulate the imagination of school-children in technology must take account of these characteristics as well as the needs and capacity of the pupils, and, like Mr. Dancy, Dr. Christopherson emphasizes that people and the relations between peoples form an essential part of the technological world. To an increasing extent, moreover, the technologist will derive his information from the social and biological sciences, from economics and psychology, as well as from the physical sciences.

It should thus be apparent that the contribution by Dr. Christopherson has some points in common with the following paper, in which Sir Edward Boyle discussed the philosophical aspects of the differentiation between pure and applied science, and whether, in fact, the differentiation was tenable. At the outset, Sir Edward made

the welcome admission that the concern with the supply of scientists and technologists in Britain's economy extended also to an adequate supply of technicians and craftsmen, and of educated men and women generally who were competent to take their place in patterns of production which were far more complex than in the past. He suggested that a clear distinction could no longer be drawn between pure and applied research, and that usually such a distinction simply reflected the motives of those who sponsored the research.

Accordingly, the question of the relations between research institutions and industry became an important aspect of the organization of civil research, and Sir Edward referred to the development in the United States of the research company as an intermediary between academic institutions and manufacturing industry. One such organization, developed by Columbia University and other universities on the east coast of the United States, is Associated Universities Incorporated. This is a non-profit corporation in the State of New York which acts as a buffer between the universities and the Federal Government, operating, for example, the Brooklyn National Laboratory on contract from the Atomic Energy Commission, and a national radio-astronomy observatory on contract from the National Science Foundation, and specializing in projects involving large facilities and staff. Sir Edward thought that this was a development that might be pursued in Britain.

It was at this stage, after remarking that the boundary between pure and applied science appeared to be subject to erosion from both sides, that Sir Edward quoted the comment by Sir Peter Medawar in his Tizard Memorial Lecture that the reverence for pure science in Britain was rather parochial and could not be sustained on philosophical grounds. The scientist, Sir Peter urged, measured the value of research by the size of its contribution to that huge, logically articulated structure of ideas, which is already, though not yet half built, the most glorious accomplishment of mankind. Admittedly, Sir Peter accepts Bacon's distinction between research that increases our power over Nature and research that increases our understanding of Nature. However, he was arguing for a critical investigation of the organization of research—not the allocation of administrative responsibilities, or the economics and logistics of science, but an investigation of the behavioural and intellectual structure of all that contributes to the enlargement of our knowledge and understanding of Nature. He was appealing for more critical and constructive thinking about all the factors that contribute to the productivity of scientists or are involved in the relations between research and its administration.

Sir Edward did not himself pursue this question, any more than he examined in further detail the organization of civil science, though in passing he emphasized the importance of working technologists remaining in close touch with the academic institutions where they were trained. Moreover, after suggesting that the relation between the pure and applied sciences was subtle and complex, he directed particular attention to the criteria used by scientists when judging the discoveries of their colleagues and the interpretations put on them—just as Sir Peter had done. Foremost among these criteria is their explanatory value—their generality, span of relevance or rank in the general hierarchy of explanation. Next is their clarifying power—the degree to which they can resolve what has hitherto been perplexing. Thirdly is

the degree of originality involved in the research—the novelty of the solution to which it led. Some weight is given to the elegance of the solution, the economy of thought and work by which it was achieved, or the magnitude of the obstacles that had to be surmounted. In Sir Peter's experience, while one scientist might say of the work of another, "How elegant", "How ingenious" or "How illuminating", its purity or usefulness was never mentioned.

Sir Edward Boyle thought the implications of this needed consideration. He believed that there were real differences between science and technology, although they had become more closely linked, but he suggested that the progress of modern technology should be seen in the perspective of the revolutionary changes in scientific thought during the early years of this century. It was in this context that he referred to the account of scientific revolutions which Prof. Kuhn gives in his book, *The Structure of Scientific Revolutions*, in which he challenges the idea that the advance of science is necessarily cumulative. On the contrary, Prof. Kuhn argues that from time to time it is necessary to change the meaning of established and familiar concepts as, for example, was necessary under the impact of Einstein's theory.

Sir Edward regarded three points made by Kuhn as being of special significance. First, we seem to be confronting frontiers of language and communication as well as of science. Kuhn considers that what occurs during a scientific revolution is not fully reducible to a misinterpretation of individual data, if only because these data are not unequivocally stable.

Secondly, he referred to Kuhn's emphasis on the role of youth in fundamental research, and also on the role of the 'invader'. The second point regarding youth was also emphasized by Prof. R. V. Jones in his Payne Memorial Lecture, while Sir Edward made the pertinent suggestion that it would be worth while examining in some detail the extent to which the 'invader' from another discipline had contributed to the development of science—including social science and industry.

Thirdly, Sir Edward directed attention to Kuhn's emphasis on "the unparalleled insulation of Nature's scientific communication from the demands of the laity and of everyday life". He agreed that it is important not to underrate the type of scientific activity that Prof. Kuhn describes and that it is a notable aspect of the growth of science in the modern world. However, Sir Edward pointed out that this kind of work at the outer frontiers of knowledge shifting over concepts or providing new constitutive principles is limited in extent. It involves only a few men of genius and perhaps only a dozen or two institutions in the world as a whole. While the balance of the research effort should always allow for such work, he challenged the idea that research should to any extent be isolated from the community. Sir Edward considered that there should be a wider understanding of research and of scientific activity both inside and outside Parliament, and that universities as a whole should be more responsive to the needs and activities of the community. It may be neither possible nor desirable to preserve rigid boundaries between pure and applied science, but although the boundary is being rapidly eroded it is not obliterated, nor is it likely to be. This should apply no less to the distinction between the scientist and technologist, and if Sir Edward dealt rather superficially with Prof. Kuhn's main argument, his address should at least contribute to a clear understanding

of the present-day relation between pure and applied science, between scientist and technologist, and the directions in which we might seek, in practice, to improve our organization.

BEHAVIOUR THERAPY

Experiments in Behaviour Therapy

Readings in Modern Methods of Treatment of Mental Disorders derived from Learning Theory. Edited by H. J. Eysenck. Pp. x+558. (Oxford, London and New York: Pergamon Press, 1964.) 100s.

The Causes and Cures of Neurosis

An Introduction to Modern Behaviour Therapy Based on Learning Theory and the Principles of Conditioning. By H. J. Eysenck and Dr. S. Rachman. Pp. xii+318. (London: Routledge and Kegan Paul, 1965.) 28s. net.

BEHAVIOUR therapy is a term for which one will look in vain in the psychological dictionaries—or the general text-books. It is also a term which carries considerable emotional overtones to many psychologists and, still more perhaps, to the average informed layman. Part of the disquiet is probably due to an at least partial misapprehension—the narrowing of the concept to cover only its most dramatic and in some ways most characteristic form, although it is by no means the most frequently used method among those that are subsumed under the general heading of behaviour therapy. I refer to aversive conditioning, or, as it is more commonly called, aversion therapy, the most widely publicized application of which has been in the treatment of alcoholism through the use of emetic drugs. 'Punishment', in the non-technical sense of the term, is a word often invoked by the hostile critic. Up to a point the imputation is just, but, as Prof. Eysenck points out in one of his own contributions to the present readings (p. 180), there are fundamental differences. In common with other varieties of behaviour therapy, aversive conditioning is based on the principles of learning theory; in other words, behaviour therapy represents a scientific approach to the problem of altering human behaviour "in the direction of greater sanity, greater happiness, and greater social usefulness" (foreword, p. ix).

Much of the basic literature on behaviour therapy has already been reprinted in Eysenck's *Behaviour Therapy and the Neuroses* (1960), to which *Experiments* is a sequel and companion volume. Understandably, therefore, the present emphasis is now on experimental studies and case reports, but there are also important papers of a general character, notably by the editor himself and by Joseph Wolpe, of the University of the Witwatersrand, to whom, incidentally, the book is dedicated. Wolpe's technique of 'systematic desensitization' is central to the first of the four parts into which the book is divided, although this section, in fact, carries the title "Reciprocal Inhibition"; the other three are devoted, respectively, to "Operant Conditioning", "Other Methods" and "Behaviour Therapy with Children". The essence of desensitization consists of, to quote the author, "presenting to the imagination of the deeply relaxed patient the feeblest item in a list of anxiety-provoking stimuli—repeatedly, until no more anxiety is evoked. The next item of the list is then presented, and so on, until, eventually, even the strongest of the anxiety-evoking stimuli fails to evoke any stir of anxiety in the patient". Wolpe claims that "... consistently ... a stimulus that evokes no anxiety when imagined in a state of relaxation will also evoke no anxiety when encountered in reality".

This is clearly a less tough-minded procedure than that of aversion therapy, and less open to criticism on grounds of callousness. It would, in fact, appear to tie up closely with the 'rational psychotherapy' of Albert Ellis which constitutes the major contribution under "Other Methods".

Rational psychotherapy is based on the view that, as Ellis puts it, "neurosis consists of stupid behaviour by an un-stupid person". Treatment, to quote again, consists of "teaching clients to organize and discipline their thinking". To the sceptic this may seem to amount to little more than the adjuration to take a grip on oneself which centuries of experience have shown to be ineffectual. Nevertheless, a high measure of success is claimed for the technique, as indeed for all the other methods described in the book. One feels that for therapy of this kind to be successful the patient must have a high level not only of motivation but also of sophistication. The same is probably true of the relaxation preparatory to desensitization, and of the imaginal processes involved in the actual desensitization. The work of Natadze and the Tbilisi school on the effect of imagined experience on perception of illusions has suggested that there are very large individual differences in the ability to evolve a 'set' on this basis, and one would welcome information on whether this might not also be true of receptiveness to desensitization.

Unlike some of Prof. Eysenck's previous volumes with similar titles, which were based entirely on work carried out at the Institute of Psychiatry or under its inspiration, the present collection of readings is culled from a wide variety of sources. In particular, the papers on operant conditioning are all of United States origin, chiefly from Indiana. The main difference from reciprocal inhibition is that while the latter claims to "cure the patient", operant conditioning usually "focuses on one specific symptom". This would appear to be more closely in line with Eysenck's often reiterated statement of his own theoretical position: that "there is no neurosis underlying the symptom, but merely the symptom itself". On this view, if the symptom is removed, the patient is cured. It is manipulation of behaviour along these lines that is the behaviour therapist's main concern. That this can be done is abundantly clear, and it is perhaps the individual role of the psychologist, *qua* psychologist and distinct from the psychiatrist, to devise and validate techniques of doing it.

The foregoing was written before *The Causes and Cures of Neurosis* came to hand, and most of what has just been said could stand equally as comment on the latter book: the authors, in fact, say many of these things in almost the same words. The book carries the sub-title "An Introduction to Modern Behaviour Therapy Based on Learning Theory and the Principles of Conditioning", and covers the same ground as the *Experiments*, with only a slight redistribution of emphasis. It may be said to stand midway between the *Experiments* and Prof. Eysenck's recent 'Pelican', and as such no doubt fulfils a different function. Nevertheless, reading the book, one has a strong feeling of *déjà vu*—the case material is familiar, and even the same photographs turn up again. Furthermore, despite its title, the book is still predominantly research-centred, and in no sense more patient-centred than Prof. Eysenck's other books. Writing in the *Experiments* (p. 3) of some work by Yates on the treatment of tics, Eysenck states: "It would be quite wrong to regard its main purpose as the alleviation of human suffering". In the next sentence but one he alludes to "the preoccupation of many psychiatrists with curing patients". It is perhaps unfair to wrench these phrases from their context, but, be that as it may, it is easy to understand why Eysenck attracts criticism as bitter as some of his own polemics against psychoanalysis. It is a pity that advocacy of behaviour therapy should so frequently be associated with attacks on other disciplines; equally it is a pity that behaviour therapy should, in some quarters at least, be equated with brain-washing, or worse. There is ample evidence in these books that it can be beneficial. Whether its theoretical foundations are unassailable is a matter for dispassionate examination. **BORIS SEMONOFF**

DRUG DOSAGE IN LABORATORY ANIMALS

• Drug Dosage in Laboratory Animals

A Handbook. By C. D. Barnes and L. G. Eltherington. Pp. 302. (Berkeley and Los Angeles: University of California Press; London: Cambridge University Press, 1964.) 64s.

DRUG *Dosage in Laboratory Animals* is an attempt to summarize doses which have been used in the common laboratory species, collected from a great many published papers in the pharmacological literature. Although costly, it is unsatisfactory in a number of ways.

The only parts of the book which are intended to be read are a two-page introduction and a nine-page account of some factors which determine drug dosage and its variability. The remainder consists of more than 200 tables, each devoted to a single drug and each divided to give columns for mouse, rat, guinea-pig, rabbit, cat, dog and monkey.

Doses are given simply as figures, one for each route of administration of which a record has been found. The tables are subdivided into horizontal sections, of which the top one in each case presents lethal doses and the others are devoted, when appropriate, to different effects of the drug in question.

The information thus presented is so highly abbreviated and so incomplete that it is hard to imagine what type of reader might find it useful. For example, anyone wishing to inject nicotine into a cat will learn only that 0.02 mg/kg intravenously is a "behavioural" dose and that 0.2 mg/kg by the same route is a "cardiovascular" one. Much of the classical work of Langley on indirect pressor and ganglion-blocking actions of nicotine was performed in cats and the doses he used would surely be appropriate here, but the only references are to a paper on "a nicotinic receptor in the CNS related to EEG arousal" (1961) and to another entitled "Homatropine Methyl-bromide: a Pharmacological Re-evaluation" (1952). Again, the only information recorded about the action of histamine in the cat is that 0.005 mg/kg intravenously is a "cardiovascular" dose. No references at all are given in this case, and one is left wondering whether the work of Dale and his colleagues on vasodilatation due to histamine and on its secondary pressor effect has been omitted from the text-books in California. Let it be added that no national bias can be detected in the matter of omissions of classical work. Doses used in the important papers of Eggleston and Hatcher on apomorphine, of Cattell and Gold on digitoxin and ouabain, and of V. E. Henderson on atropine are also absent and no references to their work are to be found.

It is, perhaps, unnecessary to point out that information does not exist to fill most of the empty spaces which the terse tabular presentation adopted creates; about 90 per cent of the table area consists of vacant duplicated rectangles. Yet, even when published dose figures do exist and are reasonably accessible from reviews and bibliographies, they have often not been included. Thus there are glaring omissions from the tables for angiotensin, digoxin, histamine, ouabain and noradrenaline (which is indexed under four names, but not as nor-adrenaline).

Most of the doses which are given carry a reference number, and one of the more valuable features of the book is its bibliography, which has 819 references, often to the recent literature. However, for a few drugs no literature references are given, all doses listed having been obtained from manufacturers (for example, digoxin and chlorothiazide). The selection of drugs in the 200 tables is comprehensive and includes unfamiliar recent compounds such as dibozane, hexocyclium, mebutamate, mepenzolate and proflidil. It is, therefore, surprising that oxytocin and vasopressin are omitted.

Further criticism must be made of the sections which list doses for use of some drugs *in vitro*. These give scarcely any information, even in the case of compounds which have been much investigated using isolated tissues, such as angiotensin, calcium chloride, carbachol, decamethonium, hexamethonium, methacholine, morphine, hyosine and tetramethyl ammonium. When doses are given, they are often uncritically high and unsubstantiated by references. If these tables could not be made more complete and more critical, they would have been better omitted. A table in the appendix which sets out the composition of physiological saline solutions for isolated organ work also has important omissions, containing no mention of Krebs-Henseleit solution, of Ringer's solutions for frog tissues, or of de Jalon's solution.

A comprehensive and critical collection of drug doses for use in the laboratory when performing animal experiments would meet a real practical need and it is a pity that this handbook falls short in many respects of what is required.

J. A. PARSONS

TEACHING IMMUNOLOGY

Immunology for Students of Medicine

By J. H. Humphrey and Prof. R. G. White. Second edition. Pp. ix + 498. (Oxford: Blackwell Scientific Publications, 1964.) 47s. 6d. net.

THE present-day medical student is fortunate in having available some informative and stimulating, and reasonably short, text-books on the pathological sciences, which not only set out basic principles but also indicate growing edges.

Immunology for Students of Medicine by two leaders in the immunological field (first published in 1963 and already now in its second edition) provides an excellent example.

The book has twelve chapters, starting with a succinct historical introduction. An account of innate immunity is followed by descriptions of the nature of circulating antibodies and how they are produced, and of the nature of antigens (with a useful amount of chemistry in both cases). Then comes a chapter on detection and measurement of antigen and antibody, followed by examples of practical uses of immunization in man. The scene then changes to hypersensitivity of the immediate and delayed types, succeeded by an account of immunological tolerance, and the final chapter on auto-immunity and its relation to human disease. Perhaps the most illuminating parts are those concerning the immunoglobulins; the mechanism of antibody production; delayed hypersensitivity; immunological tolerance; and auto-antibodies.

The style of writing is light and attractive, the production excellent, the headings and sub-headings well arranged. The inclusion of a glossary (a little expansion might be considered) is most considerate, indicating incidentally that immunologists are not averse to poaching where definitions are concerned.

The authors have wisely used detail mainly to illustrate principles (though allowing themselves more scope in their examples of prophylactic immunization and in their descriptions of diseases in which auto-immune phenomena are evident), thus avoiding a text-book on immunological diseases, and making their book very readable. Yet the human aspects are constantly emphasized. Recognizing the difficulties of the student (not to forget those of the writer) in this rapidly expanding subject, and his tendency to be scared away, they present him with conclusions where they are justified, but tell him at the same time what is not known; thus the student has stable platforms on which to rest his faith, though warned that these may be jumping-off stages for new advances. By this policy the authors should interest and instruct most of their

readers, inspire the more enquiring, and even make a few future immunologists.

In this outstanding book it is difficult to pick on faults or give suggestions for improvement. But with an eye to the next edition, the section on cellular immunity might be expanded somewhat with advantage; the allusions to the immunological aspects of tuberculosis need certain changes of emphasis in the light of recent knowledge; the general definitions of allergy, etc. (on p. 287) could be tidied up. One wonders whether the commendable desire not to clutter up the book with references (restricted at present to a list of suggested further reading), merely giving names in the text in the manner of some encyclopaedias, has gone too far.

Although Humphrey and White have had medical students primarily in mind, there is no doubt that their book should have a much broader appeal; on the one hand to practising clinicians and on the other to biochemists, microbiologists, geneticists and general biologists. With the expansion and continual re-tooling of immunological research, the number of investigators requiring at least to know the language of this branch of science must be increasing.

P. D'ARCY HART

DIAGNOSIS OF PARASITES

Microscopic Diagnosis of the Parasites of Man

By Dr. Robert B. Burrows. Pp. xii+328. (New Haven and London: Yale University Press, 1965.) 15 dollars; 105s. net.

THE author of *Microscopic Diagnosis of the Parasites of Man* is head of the Parasitology Section of the Wellcome Research Laboratories in Tuckahoe, New York, and the text of the book certainly demonstrates his wide experience of the difficulties of diagnosis of parasitic infections. The book has, he says, been written to help the inexperienced technician or the student to broaden his knowledge and it can be said at once that the text of the book will do this. Part 1 of the book deals with infections that are diagnosed by examination of the faeces, urine and sputum. It contains a valuable chapter on routine examinations and staining, and another on techniques for concentrating the eggs or larvae of helminths or the cysts or trophozoites of Protozoa, in such a manner that they are not altered by the treatments given to them. A useful chapter on the artificial cultivation of Protozoa precedes chapters on miscellaneous helminthological techniques, on the oral and genital flagellates, the oral and intestinal amoebae and other intestinal Protozoa. The intestinal helminths, Trematoda, Cestoda and Nematoda, are next dealt with, before Part 2 considers infections diagnosed by examination of blood and tissues and the techniques used to deal with these. An appendix deals with the parasites of dogs and cats and the book concludes with an author and a subject index. Each chapter concludes with a valuable bibliography, and these references to the literature will enable the reader to extend his knowledge still further.

While the text will be found invaluable, it cannot be said that the illustrations reach the high standard attained by other publications of this kind. The author rightly says that many technicians find it difficult to compare a line drawing with a specimen seen through the microscope and he has endeavoured to make this easier by using photographs of helminths throughout and elsewhere by using drawings. Unfortunately, in several examples, the material supplied by the author has not been clearly reproduced. Most of the figures bring out the very different sizes of the objects figured, and the magnifications of these are given. This is a valuable feature of the book, because it largely overcomes another difficulty that many students have—that of appreciating how big or, often, how very small are the objects they are looking for. Fig. 1,

for example, assembles in one illustration the comparative sizes of the eggs, larvae and cysts of some representative parasites, and this figure is clearly reproduced. Some other figures, on the other hand, are not. Fig. 8, for example, shows only pale ghosts of the unstained trophozoites of such important species as *Entamoeba coli* and *Entamoeba histolytica* and other intestinal amoebae. Unsatisfactory also is the photograph of *Demodex canis* in Fig. 100. With these and a few other exceptions, the illustrations are effective and useful and the failure of those mentioned is clearly not the fault of the author, to whom the sympathy of the reader will surely be extended. In other respects the book is attractively produced. The author is to be congratulated on its text, which will make the book a useful addition to the library of any laboratory concerned with the diagnosis of parasitic infections of man.

G. LAPAGE

AN INTRODUCTION TO MOLECULAR GENETICS

Microbial and Molecular Genetics

By Prof. J. R. S. Fincham. (Modern Biology.) Pp. x+149. (London: English Universities Press, 1965.) 15s. net.

DURING the past few decades many major advances have been made in the new science of molecular genetics, and the flood of original contributions in this field continues unabated. Apart from one or two advanced texts and symposia on this subject there is, to my knowledge, no introductory account. *Microbial and Molecular Genetics*, the most recent addition to the "Modern Biology" series, is intended to provide just such an introduction for biology students.

There are two obvious ways of treating the material dealt with in this book. The first takes as its starting point the physico-chemical structure of the genetic material (DNA) and from this develops the concept of the gene as a unit of structure, mutation and function. The second is the historic approach leading from genetic analysis to DNA. In choosing a path somewhere between these two, Prof. Fincham has had to sacrifice a certain degree of continuity in his text so that the student may find little to connect the material of one chapter with the next.

A short introduction which describes briefly the basic cellular processes of mitosis and meiosis is followed by a clear account of the structure and replication of DNA. It is perhaps just a little unfortunate that the manner of presentation does not lay greater emphasis on the evidence on which the identification of DNA as the genetic material rests, since historically the significance of genetic transformation with DNA was only slowly recognized, yet this and other evidence provide one of the cornerstones of molecular biology. In a chapter on mapping the genetic material, the methods of genetic analysis in a micro-organism with a sexual cycle are clearly explained and illustrated with data from *Neurospora*. The three principal mechanisms of genetic exchange between bacteria; conjugation, transduction and transformation are described and the way they can be used to construct genetic maps is explained. Finally, a brief and non-technical account is given of the genetics of bacteriophage. The chapter on mutation contains a good account of the molecular basis of chemical mutagenesis. In the chapters on gene action and its regulation, the principal concepts are clearly presented and here, as elsewhere, the author makes frequent and well-chosen use of experimental data from the literature to clarify each step in his argument. A final chapter is devoted to an account of present-day knowledge of episomes.

The text is written without reference to source material, but each chapter is provided with a carefully selected list

of references for further reading which the student will find extremely valuable.

To provide an account of microbial and molecular genetics within the compass of a slim volume which is both popular and up to date without, on one hand, oversimplifying, or, on the other hand, condensing to the point of incomprehensibility, is a difficult task. Prof. Fincham has come very close to achieving this task. But the uninitiated student would do well to follow the advice of the general editor of this series when he says, in the foreword, "This is a book that deserves and indeed requires careful reading more than once".

S. W. GLOVER

GEOLOGY OF GRANITE

Geology of Granite

By Prof. E. Raguin. Translated from the second French edition by E. H. Kranok and P. R. Eakins, with Jean M. Eakins. Pp. xxi+314. (London and New York: Interscience Publishers, a Division of John Wiley and Sons. 1965.) 68s.

ENGLISH-speaking students of geology whose knowledge of continental points of view on the granite problem has largely been derived from review articles, such as Prof. Read's "Meditations", now have the advantage of this translation of E. Raguin's often quoted text-book.

Geology of Granite, as implied by the title, aims at providing a comprehensive account of the geology of granite, including mineralogy, petrography and occurrence. The main interest, however, for most readers, will be in following the position of Prof. Raguin on the subject of granite petrogenesis, backed by many illustrative examples and an international reference list. The author bases his thesis on the recognition of two great categories of granite, circumscribed massifs (*massifs circonscrits*) and anatectic granites with migmatites; the former have sharp limits and appear to be replacements or displacements of their country rock, while the latter are vast diffuse granites which impregnate immense volumes of the Earth's crust. These diffuse granites are the result of advanced mobilization of deep-seated zones, a mobilization which resembles a partial fusion. The existence of connecting links between these two main divisions is recognized but not discussed in detail. This is unfortunate, as these connecting links are important to the concept of a granite series, a concept which evidently has the support of Prof. Raguin, but which is not developed. Indeed, the difficulty of linking the phenomena described together to form a series is well evident, and in my opinion stems from the fact that much granite has originated at depths beneath those at present exposed by erosion, and thus the connecting links of the granite series, if present, are not readily observable. It is a pity that in these matters the reader, after being introduced to many of the fundamental facts and ideas, is left to draw his own conclusions and infer those of Prof. Raguin, whose attitude throughout is one of extreme caution.

An interesting account is given of the relations between salic volcanic rocks and granitic plutons. The sub-volcanic granites are regarded as exceptional and though the relation of volcanism to plutonism is regarded as an unsolved problem, the hypothesis that there is no direct relationship of volcanic rocks and major plutons in the Earth's crust seems to be preferred. No reference is made to W. Q. Kennedy's concept of volcanic and plutonic associations or the more fruitful one of orogenic and anorogenic associations, though the common coincidence of granite and orogenesis is emphasized.

The translation is of the second French edition and there are some references quoted up to 1961. It is unfortunate that little reference is made to experimental evidence on the origin of granite, and the early work of Tuttle and

Bowen on the granite system is but briefly mentioned. The fact that this is a translation of a text originally written some years ago is also evident in various other ways. Thus, in the section dealing with the mineralogy of granite, the feldspars receive only summary treatment and the amphiboles are dealt with in five lines. Also, in recent years, there has been something of a revolution in thinking on the relation of the Earth's mantle to many problematical aspects of geology, and the incorporation of this new information, together with such other modern developments as radiometric dating and isotope geology, would completely alter many aspects of the book.

These criticisms aside, we must be grateful to the translators and publishers for making this text readily available. The granite controversy has often been bedevilled by the volume of words contributed by the disputants; this, really, is symptomatic of the fact that the concepts involved are often as nebulous as the rocks themselves. This difficulty is perhaps even greater in a translation, but nevertheless the translators are to be congratulated on producing a readable and accurate text.

P. E. BROWN

A BROAD MAGNETIC FIELD

Proceedings of the International Conference on Magnetism, Nottingham, September 1964

Pp. xvi+878. (London: The Institute of Physics and The Physical Society, 1965.) 168s.

ALTHOUGH this, the sixth international conference on 'Magnetism', attracted fewer participants than the fifth at Kyoto (1961), and the same number of papers was presented at each, yet the Nottingham conference was undoubtedly extremely successful. This fact and the greatly increased realization of the importance of magnetism as a branch of solid-state physics are clearly shown in the volume under review. Of the 228 papers delivered, the book gives 225, with one paper (by Lowde) promised, and two by other authors given in title only.

The titles of the sessions of the conference have been retained for the chapter headings, and, disregarding repetitions, these are: theory, transition metals, critical phenomena, Fermi surface, metals and alloys, rare-earth metals, neutron diffraction, spin waves, covalency and exchange effects, ferro- and antiferro-magnetism, nuclear magnetic resonance, resonance and relaxation, non-metallic ferro- and antiferro-magnetics, oxides and compounds, miscellaneous oxides, haematite, ferrites, garnets, magnetization processes, anisotropy, hard magnetic materials, thin films, electron microscopy.

Most papers, as published, show some expansion relatively to the matter actually delivered *viva voce*, but a few authors have merely re-submitted the summary circulated to all members before the first meeting. In many cases a more detailed paper is promised in a footnote. The discussions following each paper at the conference have been reported in, regrettably, very few cases, regrettably briefly, and often without the author's reply.

Now, I heard only one paper which excited neither question nor comment. Therefore, the inadequate reporting of the discussions seems to be attributable to a weakness in the recording system used, or the lack of circulated sheets for submission of comments in writing. This last was, in fact, a noticeable omission at the meeting.

Comparing the subjects of the papers with those of the two relevant volumes which appeared after the Kyoto conference reveals no world-shaking advance in magnetism, but, instead, steady progress throughout nearly the whole range of the subject. Papers appear on some techniques for the first time at these conferences; for example, the use of electron-microscopy and of metallic whiskers for domain investigation. On the other hand, interest in magnetism of rocks seems to have subsided.

The range of topics coming within the scope of 'magnetism' as a subject is now very wide, and this is fully represented in this book. Readers will, therefore, make many different selections of the most interesting or most useful paper. In spite of the much-increased availability of Russian literature these days, many readers will regard the review of "Recent Work by Soviet Physicists on the Theory of Magnetism" by Vonsovskii as particularly valuable, not least because of the 188 references given. Following a similar paper by the same author at Kyoto, this would appear to be becoming a regular feature of these conferences. The question arises whether similar reviews from elsewhere might not also be useful.

Those of us who saw the remarkable film of spin-waves in chromium tribromide shown by Dillon, Walker and Remeika will be a little disappointed by the presentation of the photographs in their paper, but one must accept the inevitable limitations.

I feel compelled, however, to criticize the presentation of the book. The enormous size (30.7 × 22.5 × 6.0 cm) and weight (2.75 kg) make it most inconvenient to read. This is a book to be studied, not referred to as is a dictionary. Dimensions and weight are, therefore, important. If each successive paper had been begun on the same page as its predecessor, and if two whole pages had not been used for each chapter heading, the bulk of the book would have been much reduced. A count of the first 100 pages reveals the equivalent of more than 20 blank pages, indicating a possible reduction of 20 per cent in size and weight. This might also have affected the price, which is nearly 50 per cent higher than that of the Kyoto proceedings, in spite of the fact that the latter also contained 400 pages on the simultaneous crystallography conference. Finally, was a cloth binding (not paper) essential, and was one volume (not three) inevitable?

Ziman¹ has cast doubt on the value of conference reports, particularly beyond the first year or two after publication. This report, however, justifies itself as well as may be. Because of the wide range of the papers given, it provides an introduction to the latest activity in many fields, and to the immediately preceding papers leading up to it. Workers compelled by the trends of their own research to cross for a time the boundary into other fields should thus find the book providing a valuable short cut to the most recent work.

J. H. DAVIS

OPTICAL ANALOGUE METHODS IN DIFFRACTION STUDIES

Optical Transforms

Their Preparation and Application to X-ray Diffraction Problems. By Dr. C. A. Taylor and Prof. H. Lipson. Pp. x+182+54 plates. (London: G. Bell and Sons, Ltd., 1964.) 45s. net.

OPTICAL transform is the name given to the pattern of diffracted light given by an object such as a group of diffracting centres, a name based on the fact that the optical diffraction pattern corresponds to the Fourier transform calculated mathematically. In short, *Optical Transforms* is about the use of optical diffraction methods in place of mathematical methods for demonstrating the basic principles of diffraction and for solving diffraction problems. The experience of the authors has been mainly in crystal structure determination from X-ray diffraction patterns, but optical analogue methods are quite generally valid for all diffraction problems.

The book starts with a historical survey of the development of these methods, from their introduction by W. L. Bragg in 1939, through their application to the solution of fully ordered crystal structures (notably sodium benzyl penicillin), to recent applications to disordered or distorted structures. There follow chapters on basic

concepts and the mathematical treatment of diffraction, on the optical apparatus necessary for observing and recording diffraction patterns (culminating in the large diffractometers used by the authors in Manchester), and on the preparation of 'masks'—sets of holes in opaque screens, representing atomic arrangements.

In the main part of the book the characteristics of optical transforms and their use in interpreting the X-ray diffraction patterns of crystals are considered in detail. The exposition here (and, indeed, throughout the book) is admirably clear, and all the points made are lavishly illustrated by many beautifully reproduced diffraction patterns. Authors and publisher deserve the highest praise for putting all this beautiful experimental material so clearly before the reader.

The educational value of this section of the book can hardly be exaggerated. By studying the examples and contemplating the diffraction patterns, the reader acquires a valuable appreciation of the reciprocal relation between the characteristics of an arrangement or pattern and those of its diffraction pattern; one grows, so to speak, a Fourier eye, and acquires some facility in the art of mentally turning things inside out—a facility which can scarcely fail to play a useful part in solving the practical problems of interpretation which confront the X-ray crystallographer. The authors justly say that the optical transform approach to diffraction emphasizes the basic physics, and observe that "this is particularly important in X-ray applications where there has been a tendency to over-emphasize the mathematical aspects". The choice of methods of approach to problems is to some extent a matter of personal taste; certainly, to those who prefer a physical rather than a mathematical approach it is refreshing to appreciate, for example, the broad principles of intensity statistics in terms of the characteristics of diffraction patterns rather than as the outcome of equations, or to see in a diffraction pattern a visual demonstration of the presence and orientation of a benzene ring or a chain of atoms.

In the latter part of the book the lessons learnt from optical analogues are applied to the solution of crystal structures from X-ray diffraction patterns; there is much useful information on practical procedures together with some detailed examples of structure determination. One of the more striking fruits of this approach is the recognition of two distinct features, such as a ring and a chain, in the same molecule, since the two features stamp their hall-marks as if independently on the diffraction pattern. The authors might have added even more striking examples: the transform concept has played an important part in revealing the helical conformation of chain polymers, notably synthetic hydrocarbons and nucleic acids—though optical analogues have been little used.

Crystallographers will ask whether optical analogue methods can play a useful part in their work, apart from the undoubted educational value. One of the reasons for the introduction of these methods—to relieve the crystallographer of the heavy burden of computation—is (for fully ordered structures) no longer operative in this age of electronic computers; and for solving the initial structure-puzzle the limitations of the methods tend to restrict their usefulness to molecules with marked regularities; nevertheless, wherever trial and error methods have to be used, the testing and above all the rational modification of trial models can be done rapidly and effectively by optical analogue methods. This book leaves one with the impression that the optical methods may be of most value in the study of distorted or partly disordered structures such as certain alloys and semi-crystalline polymers, where mathematical treatment is daunting even in the computer age. But all crystallographers, and indeed all diffractionists, whether or not they are likely to use optical analogue methods themselves, are strongly advised to read this book; they will get much pleasure and profit from it.

C. W. BUNN

Advances in Radiation Biology

Vol. 1. Edited by Leroy G. Augenstein, R. Mason and H. Quastler. Pp. x+285. (New York and London: Academic Press, 1964.) 88s.

ADVANCES in *Radiation Biology* cannot be recommended as light holiday reading. The editors say "the need is clear for a series of review articles designed to keep more of us in contact with branches of the subject other than our own", but there is a danger that what they offer will have the opposite effect, of convincing the average radiation biologist that he has no hope of grasping the physico-chemical fundamentals of his subject and of driving him to seek a soft option in some corner where such knowledge is unnecessary. For the brave, however, and none but the brave, this book is just right, though the title is an over-simplification and it should be called "Advances in Radio-bio-physico-chemistry".

It starts with a comparatively easy and clear account of the radiolysis products of water, with valuable tables of rate constants for reactions of the electron, the hydrogen atom and the hydroxyl radical, which should help to keep speculators on the rails; but even in this first chapter it foreshadows the horrors that are to come by saying, "a knowledge of rate constants . . . is only a small part of the problem. The reaction of a radical with a molecule produces a second radical. The nature of the new radical is not even known for most of the reactions given in Tables I, II and III". This prepares us, somewhat inadequately, for shocks such as the table on p. 180 showing the nineteen irradiation products of such an unreactive substance as α -aminobutyric acid.

The second chapter, on photosynthesis, though excellent, should not be included unless the title is further expanded to "Radio- and Photo- . . . etc.", because the irrational but useful convention is fully established that 'radio-' refers to 'ionizing' radiation and 'photo-' to visible light. Nevertheless, biologists who wish to get a glimmering of applied quantum mechanics, beautifully expounded, would do well to read it. After this it is restful to read that tritium has an atomic weight of three and to meet the nice compact table on pp. 110-112 summarizing the depressed growth and suicide that it causes in all sorts of biological material. The next chapter goes to the heart of the radiobiological problem, collecting all those puzzling cases where effects are produced by far smaller doses of radiation than can possibly be explained. The next chapter, on amino-acids, will break the back of all but the toughest reader, not with high-brow physics, but with its mass of empirical chemistry. The final chapter uses all the previously enunciated concepts to discuss the inactivation of enzymes, after which the reader goes on holiday with some nice non-controversial light reading such as Beilstein. J. ST. L. PHILPOT

The Systematic Identification of Organic Compounds

A Laboratory Manual. Fifth edition. By R. L. Shriner, R. C. Fuson and D. Y. Curtin. Pp. ix+458. (New York, London and Sydney: John Wiley and Sons, Inc., 1964.) 59s.

THE fifth edition of this well-known publication on the qualitative analysis of organic compounds will continue to be warmly welcomed by the student and research worker as a supreme laboratory vade-mecum.

The fundamental chemical and physical tests leading to the identification of organic compounds are lucidly described. Much attention is directed to the manner in which laboratory reports on unknown substances should be represented and there are a number of most useful examples of the final sequential system of deductive reasoning which leads to the positive identification of the unknown compound.

Excellent chapters are provided on instrumental applications, the methods of infra-red and ultra-violet

spectroscopy being succinctly demonstrated. Nuclear magnetic resonance phenomena are concisely explained with most adequate references to more advanced textbooks.

The book concludes with nearly a hundred pages of physico-chemical data associated with derivatives of hydrocarbons, amines, nitriles, etc.; a most valuable compilation, providing confirmatory evidence of identification of unequivocal character. The "Sets" of problems for students which the authors have provided must prove a most valuable educational aid. Like its predecessors, this is a first-class book for teachers and students in schools, technical colleges and universities.

D. T. LEWIS

Proceedings of the International Symposium on Chemotherapy of Cancer

Lugano, 28th April to 1st May, 1964. Edited by Prof. Placidus A. Plattner. Pp. ix+324. (Amsterdam, London and New York: Elsevier Publishing Company, 1964.) 75s.

IN the *Proceedings of the International Symposium on the Chemotherapy of Cancer*, organized by the Swiss Academy of Medical Sciences, the editorial hand of Prof. P. A. Plattner has rested lightly on his expert contributors. This results in a volume in which the individual styles of the authors are retained, as is the sense of occasion, so that, provided the reader approaches the book in the spirit in which it has been compiled, he is carried easily through it.

The subject of the symposium is well and authoritatively covered. There are chapters on the biochemistry and modes of action of alkylating agents and antimetabolites, on clinical experience with established drugs, laboratory and clinical reports on a number of newer ones, and a section entitled (perhaps unhappily) "Selective Toxicity of Anti-Tumor Compounds", in which the toxic effects due to non-specificity of action are clearly and frankly set out. It is hoped that the decision of the organizers to include in this symposium a paper on polyoma virus and its oncogenic action will not result in an interesting review article being missed by some who would profit from it.

This, clearly, is a book to be read by all those engaged with problems of the treatment of cancer, whether in the laboratory or in the ward. It is also to be commended to workers in the basic sciences who, by reading what is written, noting what is not, and examining critically each assumption (both stated and implied) made throughout the book, may well find pointers to help them to provide the fundamental information on which a rational and successful therapy may be based. D. C. ROBERTS

Elements of the Natural Movement of Population

By Egon Vielrose. Translated from the Polish by I. Dobosz. Translation edited by H. Infeld and P. F. Knightsfield. Pp. 288. (London and New York: Pergamon Press; Warszawa: Panstwowe Wydawnictwo Ekonomiczne, 1965.) 70s. net.

ELEMENTS of the *Natural Movement of Population* is neither an introduction to demographic analysis nor an outline of the development of world population nor an attempt to explain differential rates of growth. It consists of an extensive commentary on selected vital statistics, dealing with population structure, fertility, nuptiality and mortality. It is largely derivative and little attempt is made to take account of post-war advances in demography. Moreover, the vital statistics discussed are used rather uncritically and with little attempt to assess the adequacy of the system by which they are collected. To give but one random example, on p. 146 the average numbers of live births per female in Angola and Australia are given side by side without any indication of the relative reliability of the data. E. GREBENIK

BIOLOGICAL AND MENTAL EVOLUTION: AN EXERCISE IN ANALOGY*

By ARTHUR KOESTLER

ALLOW me to take you on a ride on the treacherous wings of analogy, starting with an excursion into genetics. Creativity is a concept notoriously difficult to define; and it is sometimes useful to approach a difficult subject by way of contrast. The opposite of the creative individual is the pedant, the slave of habit, whose thinking and behaviour move in rigid grooves. His biological equivalent is the over-specialized animal. Take, for example, that charming and pathetic creature, the koala bear, which specializes in feeding on the leaves of a particular variety of eucalyptus tree and on nothing else; and which, in lieu of fingers, has hook-like claws, ideally suited for clinging to the bark of the tree—and for nothing else. Some of our departments of higher learning seem expressly designed for breeding koala bears.

Sir Julian Huxley has described over-specialization as the principal cause why evolution in all branches of the animal kingdom—except man's—seems to have ended either in stagnation or in extinction. But, having made his point, he drew a conclusion which you may find less convincing. "Evolution," he concluded, "is thus seen as an enormous number of blind alleys with a very occasional path to progress. It is like a maze in which almost all turnings are wrong turnings¹." With due respect, I think this metaphor is suspiciously close to the old-fashioned behaviourist's views of the rat in the maze as a paradigm of human learning. In both cases the explicit or tacit assumption is that progress results from a kind of blind man's buff—random mutations preserved by natural selection, or random tries preserved by reinforcement—and that that is all there is to it. However, it is possible to dissent from this view without invoking a *deus ex machina*, or a Socratic *daimon*, by making the simple assumption that, while random events no doubt play an important part in the picture, that is not all there is to it.

One line of escape from the maze is indicated by a phenomenon known to students of evolution by the ugly name of paedomorphism, a term coined by Garstang² some forty years ago. The existence of the phenomenon is well established; but there is little mention of it in the text-books, perhaps because it runs against the *Zeitgeist*. It indicates that in certain circumstances evolution can re-trace its steps, as it were, along the path which led to the dead-end and make a fresh start in a more promising direction. To put it simply, paedomorphism means the appearance of some evolutionary novelty in the larval or embryonic stage of the ancestral animal, a novelty which may disappear before the adult stage is reached, but which reappears in the adult descendant. This bit of evolutionary magic is made possible by the well-known mechanism of neoteny, that is to say, the gradual retardation of bodily development beyond the age of sexual maturity, with the result that breeding takes place while the animal still displays larval or juvenile features. Hardy³, de Beer⁴ and others have pointed out that if this tendency toward 'prolonged childhood' were accompanied by a corresponding squeezing out of the later adult stages of ontogeny, the result would be a rejuvenation and de-specialization of the race which would thus regain some of its lost adaptive plasticity. But of even greater importance than this re-winding of the biological clock is the fact that in the paedomorphic type of evolution selective pressure operates on the early, malleable stages of ontogeny. In contrast to this, gerontomorphism—the

appearance of novel characters in the late-adult stages—can only modify structures which are already highly specialized. One is accordingly led to expect that the major evolutionary advances were due to paedomorphism and not to gerontomorphism—to changes in the larval or embryonic, and not in the adult, stage.

Let me give an example, which will make clearer what I am driving at. There is now strong evidence in favour of the theory, proposed by Garstang² in 1922, that the chordates, and thus we, the vertebrates, descended from the larval state of some primitive echinoderm, perhaps rather like the sea-urchin or sea-cucumber. Now an adult sea-cucumber would not be a very inspiring ancestor—it is a sluggish creature which looks like an ill-stuffed sausage, lying on the sea-bottom. But its free-floating larva is a much more promising proposition: unlike the adult, it has bilateral symmetry, a ciliary band presumed to be the forerunner of the neural fold, and other sophisticated features not found in the adult animal. We must assume that the sedentary adult residing on the sea-bottom had to rely on mobile larvae to spread the species far and wide in the ocean, as plants scatter their seeds in the wind; and that the larvae, which had to fend for themselves, exposed to much stronger selective pressures than the adults, gradually became more fish-like; and lastly became sexually mature while still in the free-swimming, larval state—thus giving rise to a new type of animal which never settled on the bottom at all and altogether eliminated the senile, sessile cucumber stage from its life-history.

It seems that the same re-tracing of steps to escape the dead-ends of the maze was repeated at each decisive evolutionary turning-point—the last time, so far as we know, when the line which bore our own species branched off from some ancestral primate. It is now generally recognized that the human adult resembles more the embryo of an ape than an adult ape. In both, the ratio of brain-weight to body-weight is disproportionately high; in both, the closing of the sutures of the skull is retarded to allow for further brain growth. The back to front axis through man's head—the direction of his line of sight—forms an angle of ninety degrees with his spinal column; a condition which, in apes and other mammals, is only found in the embryonic stage. The same applies to the angle between the uro-genital canal and the backbone, which accounts for the singularity of the human way of mating. Other embryonic—or, to use Bolck's⁵ term, foetalized—features are the absence of brow-ridges, scantiness of body-hair, retarded development of the teeth, and so on. As Haldane⁶ has said: "If human evolution is to continue along the same lines as in the past, it will probably involve a still greater prolongation of childhood and retardation of maturity. Some of the characters distinguishing adult man will be lost." But there is a reverse to the medal, which Aldous Huxley gleefully showed us in *After Many A Summer*: artificial prolongation of the absolute life-span of man might provide an opportunity for features of the adult ape to re-appear in Methuselah. But this only by the way.

The essence of the process which I have described is a retreat from highly specialized adult forms of bodily structure and behaviour to an earlier, more plastic and less committed stage—followed by a sudden advance in a new direction. It is as if the stream of life had momentarily reversed its course, flowing uphill for a while, then opened up a new stream-bed—leaving the koala bear stranded on its tree like a discarded hypothesis. We have now reached the crucial point in our excursion,

* Substance of an address delivered on September 18 at the Bicentennial Celebration commemorating the birth of James Smithson, held in Washington during September 16–18 (see *Nature*, 208, 320; 1965).

because it seems to me that this process of *reculer pour mieux sauter*—of drawing back to leap, of undoing and re-doing—is a basic feature of all significant progress, both in biological and mental evolution.

It can be shown, I think, that these two types of progress—the emergence of biological novelties and the creation of mental novelties—are analogous processes on different levels of the developmental hierarchy. But to demonstrate the connexion we must proceed stepwise from lower to higher organisms. One of the fundamental properties of living organisms is their power of self-repair, and the most dramatic manifestations of this power are the phenomena of regeneration (which Needham⁷ called “one of the more spectacular pieces of magic in the repertoire of living organisms”). Primitive creatures, like flatworms, when cut into slices, can regenerate a whole animal from a tiny fragment; Amphibia can regenerate limbs and organs; and once more the ‘magic’ is performed by *reculer pour mieux sauter*—the regression of specialized tissues to a genetically less committed, quasi-embryonic stage, a de-differentiation or de-specialization followed by a re-differentiation.

Now the replacement of a lost limb or lost eye is a phenomenon of a quite different order from the adaptive processes in a normal environment. Regeneration could be called a meta-adaptation to traumatizing challenges. The power to perform such meta-adaptations manifests itself only when the challenge exceeds a critical limit and can only be met by having recourse to the genetic plasticity of the embryonic stage. We have just seen that the major phylogenetic changes were brought about by a similar retreat from adult to embryonic forms. Indeed, the main line of development which led up to our species could be described as a series of operations of phylogenetic self-repair: of escapes from blind alleys by the undoing and re-moulding of maladapted structures.

Evidently, self-repair by the individual produces no evolutionary novelty, it merely restores the *status quo ante*. But that is all the individual needs in order to regain its normal adaptive balance in a static environment (assuming that the traumatizing disturbance was only a momentary one). Phylogenetic ‘self-repair’, on the other hand, implies changes in the genotype to restore the adaptive balance in a changing environment.

As we move toward the higher animals, the power of regenerating physical structures is superseded by the equally remarkable power of the nervous system to re-organize its mode of function. (Ultimately, of course, these reorganizations must also involve structural changes of a fine-grained nature in terms of circuitry, molecular chemistry or both, and so we are still moving along a continuous line.) Lashley⁸ taught his rats certain visual discrimination skills; when he removed their optical cortex, the learning was gone, as one would expect; but, contrary to what one would expect, the mutilated rats were able to learn the same tasks again. Some other brain area, not normally specializing in visual learning, must have taken over this function, deputizing for the lost area.

Similar feats of meta-adaptation have been reported in insects, birds, chimpanzees and so on. But let us get on to man, and to those lofty forms of self-repair which we call self-realization, and which include creativity in its broadest sense. Psycho-therapy, ancient and modern, from shamanism down to contemporary forms of abreaction therapy, has always relied on what Ernst Kris⁹ has called “regression in the service of the ego”. The neurotic with his compulsions, phobias and elaborate defence-mechanisms is a victim of maladaptive specialization—a koala bear hanging on for dear life to a barren telegraph pole. The therapist’s aim is to regress the patient to an infantile or primitive condition; to make him retrace his steps to the point where they went wrong, and to come up again, metamorphosed, re-born. Goethe’s *Stirb und Werde*, the inexhaustible variations of the

archetype of death and resurrection, dark night and spiritual rebirth, all revolve around this basic paradigm—Joseph in the well, Jesus in the tomb, Buddha in the desert, Jonah in the belly of the whale.

There is no sharp dividing line between self-repair and self-realization. All creative activity is a kind of do-it-yourself therapy, an attempt to come to terms with traumatizing experiences. In the scientist’s case the trauma is some apparent paradox of Nature, some anomaly in the motion of the planets, the sting of data which contradict each other, disrupt an established theory, and make nonsense of his cherished beliefs. In the artist’s case, challenge and response are manifested in his tantalizing struggle to express the inexpressible, to conquer the resistance of his medium, to escape from the distortions and restraints imposed by the conventional styles and techniques of his time.

In other words, the so-called revolutions in the history of both science and art are successful escapes from blind alleys. The evolution of science is neither continuous nor strictly cumulative except for those periods of consolidation and elaboration which follow immediately after a major breakthrough. Sooner or later, however, the process of consolidation leads to increasing rigidity and orthodoxy, and so into the dead-end of over-specialization. The proliferation of esoteric jargons which seems to characterize this phase reminds one sometimes of the monstrous antlers of the Irish elk, and sometimes of the neurotic’s elaborate defence-mechanisms against the threats of reality. Eventually, the process leads to a crisis, and thus to a new revolutionary break-through—followed by another period of consolidation, a new orthodoxy, and so the cycle starts again.

In the history of art, this cyclic process is even more obvious: periods of cumulative progress within a given school and technique end inevitably in stagnation, mannerism or decadence, until the crisis is resolved by a revolutionary shift in sensibility, emphasis, style.

Every revolution has a destructive and a constructive aspect. In science the destruction is wrought by jettisoning previously unassailable doctrines, including some seemingly self-evident axioms of thought. In art, it involves an equally agonizing re-appraisal of accepted values, criteria of relevance, frames of perception. When we discuss the evolution of art and science from the historian’s detached point of view, this un-doing and re-doing process appears as a normal and inevitable part of the whole story. But when we focus our attention on any concrete individual who initiated a revolutionary change, we are immediately made to realize the immense intellectual and emotional obstacles he had to overcome. I mean not only the inertial forces of society; the primary locus of resistance against heretical novelty is inside the skull of the individual who conceives of it. It reverberates in Kepler’s agonized cry when he discovered that the planets move in elliptical pathways: “who am I, Johannes Kepler, to destroy the divine symmetry of the circular orbits!”. On a more down-to-earth level the same agony is reflected in Jerome Bruner’s¹⁰ experimental subjects who, when shown for a split second a playing card with a black queen of hearts, saw it as red, as it should be; and when the card was shown again, reacted with nausea at such a perversion of the laws of Nature. To unlearn is more difficult than to learn; and it seems that the task of breaking up rigid cognitive structures and reassembling them into a new synthesis cannot, as a rule, be performed in the full daylight of the conscious, rational mind. It can only be done by reverting to those more fluid, less committed and specialized forms of ideation which normally operate in the twilight below the level of focal awareness. Such intervention of unconscious processes in the creative act is now generally, if sometimes reluctantly, accepted even by behaviourists with a strong positivist bias. Allow me, therefore, to take it for granted that in the period of incubation—to use Graham Wallis’s¹¹

term—the creative individual experiences a temporary regression to patterns of thinking which are normally inhibited in the rational adult.

But it would be a gross over-simplification to identify—as is sometimes done—these patterns with Freud's so-called "Primary Process". The primary process is supposedly devoid of logic, governed by the pleasure principle, apt to confuse perception and hallucination, expressed in spontaneous action, and accompanied by massive affective discharge. I believe that between this very primary process, and the so-called secondary process governed by the reality principle, we must interpolate a whole hierarchy of cognitive structures which are not simply mixtures of primary and secondary processes, but are autonomous systems in their own right, each governed by a distinct set of rules. The paranoid delusion, the dream, the daydream, free association, the mentality of children at various ages and of primitives at various stages, should not be lumped together, for each has its own logic or rules of the game. But while clearly different in many respects, all these forms of ideation have certain features in common, since they are ontogenetically, and perhaps phylogenetically, older than those of the civilized adult. I have elsewhere¹² called them "games of the underground", because if not kept under restraint they would play havoc with the routines of disciplined thinking. But under exceptional conditions, when disciplined thinking is at the end of its tether, a temporary indulgence in these underground games may suddenly produce a solution which was beyond the reach of the conscious, rational mind—that new synthesis which Poincaré¹³ called the happy combination of ideas, and which I like to call 'bisociation' (as distinct from associative routine). I have discussed this process in some detail in a recent book¹² and shall not dwell on its intricate details. The point I want to make here is that the creation of novelty in mental evolution follows the same pattern of *reculer pour mieux sauter*, of a temporary regression to a naive or juvenile level, followed by a forward leap, which we have found in biological evolution. We can carry the analogy further and interpret the Aha reaction, or 'Eureka' cry, as the signal of a happy escape from a blind alley—an act of mental self-repair, achieved by the de-differentiation of cognitive structures to a more plastic state, and the resulting liberation of creative potentials—the equivalent of the release of genetic growth-potentials in regenerating tissues.

It is a truism to say that in mental evolution social inheritance replaces genetic inheritance. But there is a less trivial parallel between phylogenesis and the evolution of ideas: neither of them proceeds along a continuous curve in a strictly cumulative manner. Newton said that if he saw farther than others it was because he stood on the shoulders of giants. But did he really stand on their shoulders or some other part of their anatomy? He adopted Galileo's laws of free fall, but rejected Galileo's astronomy. He adopted Kepler's planetary laws, but demolished the rest of the Keplerian edifice. He did not take as his point of departure their completed 'adult' theories, but retraced their development to the point where it had gone wrong. Nor was the Keplerian edifice built on top of the Copernican structure. That ramshackle structure of epicycles he tore down and kept only its foundations. Nor did Copernicus continue to build where Ptolemy had left off. He went back two thousand years to Aristarchus. The great revolutionary turns in the evolution of ideas have a decidedly paedomorphic character. The new paradigm, to use Thomas Kuhn's¹⁴ term, which emerges from the revolution is not derived from a previous adult paradigm; not from the aged sea-urchin but from its mobile larva, floating in the currents of the ocean. Only in the relatively peaceful periods of consolidation and elaboration do we find gerontomorphism—small improvements to a fully mature body of knowledge. In the history of art the process is again all too obvious; there is no need to elaborate on it.

I began with a wiseful remark about the treacherous wings of analogy, aware of the fact that those who trust these waxen wings usually share the fate of Icarus. But it is one thing to argue from analogy, and quite another to point to an apparent similarity which has perhaps not been paid sufficient attention, and then to ask whether that similarity has some significance or whether it is trivial and deceptive. I believe that the parallel between certain processes underlying biological and mental evolution has some significance. Biological evolution could be described as a history of escapes from overspecialization, the evolution of ideas as a series of escapes from the bondage of mental habit; and the escape-mechanism in both cases is based on the same principles. We get an inkling of them through the phenomena of regeneration—the remoulding of structures and reorganization of functions—which only enter into action when the challenge exceeds a critical limit. They point to the existence of unsuspected 'meta-adaptive' potentials which are inhibited or dormant in the normal routines of existence, and, when revealed, make us sometimes feel that we move like sleepwalkers in a world of untapped resources and unexplored possibilities.

It could be objected that I have presented a reductionist view; that it is sacrilegious to call the creation of a Brahms symphony or of Maxwell's field equations an act of self-repair, and to compare it with the mutation of a sea-squirt larva, the regeneration of a newt-tail, the re-learning process in the rat or the rehabilitation of patients by psycho-therapy. But I think that such a view is the opposite of sacrilegious. It points, however tentatively, at a common denominator, a factor of purposiveness, without invoking a *deus ex machina*. It does not deny that trial and error are inherent in all progressive development. But there is a world of difference between the random tries of the monkey at the typewriter, and the process which I called, for lack of a better name, *reculer pour mieux sauter*. The first means reeling off all possible responses in the organism's repertory until the correct one is hit on by chance and stamped in by reinforcement. The second may still be called trial and error, but of a purposive kind, using more complex, sophisticated methods: a groping and searching, retreating and advancing towards a goal. "Purpose," to quote Herbert J. Muller¹⁵, "is not imported into Nature and need not be puzzled over as a strange or divine something. . . . It is simply implicit in the fact or organisation." This directiveness of vital processes is present all along the line, from conscious behaviour down to what Needham⁷ called "the striving of the blastula to grow into a chicken". How tenacious and resourceful that striving has been demonstrated by experimental embryology, from Speeman to Paul Weiss—though its lessons have not yet been fully digested.

Thus to talk of goal-directedness or purpose in ontogeny has become respectable again. In phylogeny the monkey still seems to be hammering away at the typewriter, perhaps because the crude alternatives that had been offered—amorphous entelechies, or the Lysenko brand of Lamarckism—were even more repellent to the scientific mind. On the other hand, some evolutionary geneticists are beginning to discover that the typewriter is structured and organized in such a way as to defeat the monkey, because it will print only meaningful words and sentences. In recent years the rigid, atomistic concepts of Mendelian genetics have undergone a softening process and have been supplemented by a whole series of new terms with an almost holistic ring. Thus we learn that the genetic system represents a "micro-hierarchy" which exercises its selective and regulative control on the molecular, chromosomal and cellular level; that development is "canalized", stabilized by "developmental homeostasis" or "evolutionary homeostasis"¹⁶ so that mutations affect not a single unit character but a "whole organ in a harmonious way"¹⁷, and, finally, that these various forms of 'internal

selection" create a restricted "mutation spectrum"¹⁸ or may even have a "direct, moulding influence guiding evolutionary change along certain avenues"¹⁹—and all this happens long before external, Darwinian selection gets to work. But if this is the case, then the part played by a lucky chance mutation is reduced to that of the trigger which releases the co-ordinated action of the system; and to maintain that evolution is the product of blind chance means to confuse the simple action of the trigger, governed by the laws of statistics, with the complex, purposive processes which it sets off. Their purposiveness is manifested in different ways on different levels of the hierarchy, from the self-regulating properties of the genetic system through internal and external selection, culminating perhaps in the phenomena of phylogenetic self-repair: escapes from blind alleys and departures in new directions. On each level there is trial and error, but on each level it takes a more sophisticated form. Some twenty years ago, Tolman and Krechevsky²⁰ created a stir by proclaiming that the rat learns to run a maze by forming hypotheses; soon it may be permissible to extend the metaphor and to say that evolution progresses by making and discarding hypotheses.

Any directive process, whether you call it selective, adaptive or expectative, implies a reference to the future. The equifinality of developmental processes, the striving of the blastula to grow into an embryo, regardless of the obstacles and hazards to which it is exposed, might lead the unprejudiced observer to the conclusion that the pull of the future is as real and sometimes more important

than the pressure of the past. The pressure may be compared to the action of a compressed spring, the pull to that of an extended spring, threaded on the axis of time. Neither of them is more or less mechanistic than the other. If the future is completely determined in the Laplacian sense, then there is nothing to choose between the actions of the two springs. If it is indeterminate in the Heisenbergian sense, then indeterminacy works in both directions, and the distant past is as blurred and unknowable as the future; and if there is something like a free choice operating within the air-bubbles in the stream of causality, then it must be directed towards the future and oriented by feed-back from the past.

HISTORY AS THE ORGANIZATION OF MAN'S MEMORY*

By PROF. HERBERT BUTTERFIELD

Master of Peterhouse, University of Cambridge

WE often think of Western civilization as scientific, and we do not always remember that it is equally remarkable for being so historically minded. In both respects the only parallel to it is ancient China—so wonderful in its science and technology, but possessing also a historical literature of almost incredible vastness. Even in China there did not develop those modern techniques which, in our section of the globe, led to the scientific revolution of the seventeenth century and the somewhat parallel historiographical revolution in the nineteenth. In both fields the developments in Europe were unique; and the Chinese have had to become pupils of the West.

Some civilizations, like that of ancient India, seem to have been governed by religions or philosophies which deny significance to the facts of history as such, and the sequence of events in time. Yet, between a culture which has soaked itself in historical memories and one for which the past is only chance and change—only bubble and froth—there must develop great differences in general mentality, in intellectual habits, and in the degree of control that can be acquired over the course of events: and the differences must extend to still deeper things that affect the very nature of the human consciousness.

Our interest in the past—our very sense for the past—(like our prowess in the natural sciences) is therefore a thing that requires to be explained. Even the case that we to-day might make for the study of history would have no meaning for those earlier generations of mankind that gave the start to the whole endeavour. We of the twentieth century might say that a society is going to be

very constricted in its development unless it looks behind itself, organizes its memory, reflects on its larger and longer experiences, learns to measure the direction in which it is moving, and gets some notion of long-term tendencies which have been observed. But this kind of diagnosis—this way of learning where we stand in the processes of time—is a thing that comes only late in the day, when civilization and scholarship itself have progressed very far. Nobody could have known in advance that by the study of the past we should be able to examine the processes of things in time. Indeed, until the world was fairly mature, nobody could even have guessed that there existed such things as historical processes which might call for analysis.

It is possible that, in every age and society, children will love to listen to the tales of a grandfather and will look back at least to the time just before they were born. All the world seems to love a story, and, even if there were no inferences to be drawn from it, we are all likely to be interested in the account by Arthur M. Schlesinger, jun., of the expedition to the Bay of Pigs—interested in it purely as the narrative of something that actually happened. I suspect that, however scientific and analytical and statistical historical scholarship may become in the latter half of the twentieth century, a great mass of people will go on loving this narrative history—the history that tells of men and their vicissitudes. Perhaps these are the people who will keep the subject sane—keep history an important humanistic factor in our civilization. But, though the telling of stories may awaken an interest in the past, it is not likely in itself to alter the structure of our mentality. Also, it is scarcely enough in itself to drive the mind to research and criticism and the passionate quest for truth. The *raconteur* knows

* Substance of an address delivered at the Bicentennial Celebration commemorating the birth of James Smithson, held in Washington during September 16–18 (see *Nature*, 208, 320; 1965).

that if he investigates the truth of the matter, he is only too likely to lose a good story.

Before writing began, the past would seem to have been just a rag-bag of old myths and stories—on the whole, a jumble of things that happened 'once upon a time'. An essential progress was achieved when the mind learned to project itself into that forest of data, and began to acquire some sense of the distances involved. It was necessary that time should be turned into something like a long tape-measure, with markings that roughly indicated succession and duration and degrees of remoteness. This is not easily achieved by peoples who have not learned to serialize or particularize the years by numbering them in the way which we are accustomed to doing. Fortunately, our distant ancestors appear to have had a mania for making lists. Some of these lists are in a sense the beginnings of history, just as others, which perform a preliminary work of classification, are in a sense the beginning of the natural sciences. It was when they put together their lists of successive kings or priests that these ancient peoples acquired their first impressions of the tremendous stretch of time behind them. The ancient Greeks had very defective lists and thought that only a comparatively short period separated them from the age when the gods had walked and sported on the Earth. But some of them learned about the huge lists of Egyptian priests and came to realize that there had been thousands of years of human history before their day. If the whole of this is taken together, it involves a change in what it means to have an existence in time—in a time which stretches behind and before.

It is comparatively easy for an individual to keep some recollection of his own personal past; but the difficulties are great if the human race or the body politic wants to achieve and organize and refine its collective memory. In the civilization of ancient Mesopotamia the arts had reached a remarkable level, and technology had done wonderful things before there existed any serious history. Even in the modern centuries the development of historical scholarship has proceeded at a slower pace than that of the natural sciences; and the intellectual revolution—with the modern techniques of discovery—comes in the nineteenth rather than the seventeenth century. In generations which were capable of the most profound philosophy and the most abstruse mathematics there would flourish a remarkable credulity about the records and stories of the past. In the middle of the nineteenth century, when the archives of the European capitals were being opened, a great stimulus was given to the subject—men felt that now, at least, they could really get down to the study of history. For centuries before that, they had more or less accepted the history provided for them, but it is not clear that they committed their souls to it, except where it was guaranteed by revealed religion. They would scarcely realize how many of the facts of history were going to be capable of more secure establishment in the future.

So it seems that Homer was accepted as history at first—the only available account—though the Greeks had not yet scrutinized very carefully their notion of historicity. For the knowledge of these early periods it was perhaps a handicap that in Homer they possessed such an impressive substitute for history. The epics were so regarded as the genuine article that the first serious attempts at historical criticism were directed at their contents. There was no possibility of discovering dates, but family trees were important, and some of the Greek noble families claimed descent from epic heroes. Here legend and history seem to meet. It would appear to be genealogy which first called for investigation.

The remoter periods always presented special difficulties. It was no easy matter to recover recollections that had once been lost. A short-term memory was a more practicable affair, however; and the more serious kind of history developed through the recording of recent

events. It is possible that in every age and society men refer to the past—if only to the recent past—for the understanding of present-day problems and even for their very formulation. Because we ourselves have become so historically minded, and because we have come to be so aware of the continuity of processes in history, we carry this tendency almost infinitely further than our distant forefathers took it. Whether we are discussing Vietnam or the incidence of prostitution, we slip into a kind of historical retrospect before we are aware of what we are doing. With us at least, it seems that talk about the present slides almost insensibly into talk about the past. But even thousands of years ago—and even before the existence of historical study—the same tendency is visible on occasion and it operated as a stimulus to historiography. One of the earliest pieces of historical narrative that we possess is a royal account of a quarrel over a frontier. The victor in the conflict, as he announced its settlement and laid out his case, referred back to the original fixing of the boundary and the successive infringements of it by his enemy. Some of the most remarkable examples of historical writing in the ancient world come from the Hittites, who, centuries before any part of the Old Testament had been written, provided their peace-treaties with historical preambles, and would even produce a similar résumé to explain an act of governmental policy. The very considerable historical literature of ancient Egypt and Assyria was the work of people who showed no sign of having any real interest in the past. It came from monarchs who desired to place on record their own building achievements, their prowess in the hunt and their victories in battle. What they intended was either to overawe their contemporaries or to make sure of their future fame or to express their gratitude to the gods. There developed, therefore, the history of the type of commemorative tablet, and it was produced on a massive scale, sometimes with elaborate literary ornament, but it was bound to lead to a dead end. At the same time, it remained true for thousands of years that the history which most gripped the rails and came closest to authenticity was that which men wrote about the events in which they had taken part or which they had more or less observed. The attempt to reconstruct a distant past from raw materials—from literary and archaeological survivals—is, on the whole, a remarkably modern enterprise. The best history was like that of Thucydides—like that of Winston Churchill, giving his account of the great wars in which he had taken part. Those who undertook to write about remoter periods relied to a considerable degree on the men who in those periods had narrated what we call contemporary history. It was in the year 1824 that Ranke produced quite a milestone in the history of historiography by demonstrating that it was not a satisfactory thing to take one's account of a given period from the writer of that period, the men who had written "histories of their own times".

The Old Testament brought things to a new stage. It envisaged the whole of mankind from the Creation and then presented a full-length national history. The influence of its presiding idea helped to give shape to what became the Western view of the time-process.

The ancient Hebrews had been a semi-nomadic people, and it was characteristic of such clans that they yearned to enter the territory of the sedentary populations and share the benefits of settled agricultural life. They expected their god to vindicate himself by procuring this; and the most vivid of the Hebrew folk-memories concerned the way in which they had been brought out of the land of Egypt to the country of the Promise. By all the rules of the game they ought to have then proceeded to adopt the Nature gods and the fertility rites of settled agricultural peoples; but their semi-nomadic beliefs prevailed—they turned from the gods of Nature to the God of history. When others had ceremonies for the cycle of the seasons, they preferred to celebrate

historical events. If young people asked why they should obey the commandments, the answer was "Because God brought us up out of the land of Egypt". They stressed the fact that their God had kept his Promise; and the Promise was a developing thing, always turning out to be something higher than had previously been thought. Also their nation was to be blessed by heaven at the finish. History pointed to a grand consummation some time.

History, then, was not merely cyclic—mere aimless revolving and vain repetition. The ancient Hebrews would insist on occasion that God, besides being the original Creator, could go on doing new things, as time proceeded. Christianity itself emerged as a 'historical' religion in a peculiarly technical sense of the words. We can see the way in which St. Augustine decided that the cyclic view of history was incompatible with Christianity. The West developed under the presidency of these Jewish ideas and for more than fifteen hundred years the men of Europe could learn about their religion only through a Bible that was packed with history.

Later ages have seen in the Old Testament almost an adumbration of the future idea of progress. Towards the end of the seventeenth and in the eighteenth centuries this idea was superseding Greek cyclic views and the belief that the natural processes of time bring decadence. The change was partly due to the realization of the accumulating achievements of the sciences and technology. But the general idea of progress may have involved an element of faith—a belief in the future, almost the notion of history as based on the Promise. Once the idea of progress had emerged it gave a further stimulus to the study of history itself. Now it was possible to organize the memory a little more, to give shape to the human story, and to see the whole in terms of development. It was possible to put to history a further range of questions. One could ask it to show how mankind, from its primitive beginnings, had come to its present civilized state.

There was a sense in which men had always gone to history for answers to questions; and almost before they had any history they would investigate genealogies, as we have seen. At the next stage, certain miscellaneous problems tended to attract them. We meet these in ancient Mesopotamia, in the Old Testament, among the ancient Greeks, in Renaissance Europe, and elsewhere. Once the initial curiosity had been aroused, the same type of question seems to have been presented everywhere. People wanted to know why mankind had been divided into nations and why, among the nations, there was such a confusion of tongues. They asked how tribes and cities and rivers had got their names. They wondered why a certain place—a well or a mountain perhaps—had come to be considered sacred. At this stage of their development, the question would be answered by the telling of a story. In ancient Babylonia the priests rather than the monarchs were responsible for the records and they tended to bring history closer to the problems of human destiny. Here one particularly observes the device of explaining things by giving an account of their origins—in other words, producing a myth.

It was in ancient Greece that questions began to be answered more effectively: and the advance was connected with a wider rationalizing movement, a great development in what we should call the sciences. It was assisted by the fact that an interest in neighbouring countries had led to geographical and ethnographical studies; and history emerged in Greece as almost the by-product of these. It made its appearance in a more scientific context; and there was a disposition to account for both geographical and historical phenomena on more naturalistic lines. The belief that the gods constantly interfered in the course of events must hitherto have obstructed the discovery of laws and processes in history.

The leadership of the Greeks became most important, however, in the scientific use of the facts that the historian

establishes; and this came to Europe at the Renaissance. They learned to extract from all the complexity of material certain types of data that could be usefully collated with one another. A famous example of this was followed also by Machiavelli when he was setting out to show that politics should be handled in a scientific manner. It involved a comparative study of all the conspiracies of history, from which it was possible, for example, to discover maxims for men who wanted to assassinate their king. Perhaps the most famous and successful use of this method is the case of the Marxists studying all the revolutions of history for the purpose of arriving at a proper technique of revolution; Richelieu and Napoleon are among the men who claimed to have studied historical examples in order to learn maxims of policies. For centuries, from the time of the Renaissance, the promoters of historical study insisted that it provided a training in statesmanship.

But the more scientific treatment which the Greeks tried to give to established historical data—the hunt for correspondences and correlations—led in the long run to a different way of thinking and talking about man's activity in the world, a different sense of the part that he plays in the unrolling of time. It brought into existence the consciousness of the processes that take place in the course of human history. For the political analyst, the City-States of Greece were excellent laboratory specimens, where the processes (the transition from monarchy to democracy, for example) took place on a comparatively small scale—not too complicated by other things, fairly visible to the naked eye, and telescoped into a reasonably short period of time. The processes could be examined and, for example, it was not the modern Marxists but the world of classical antiquity that first brought out the significance of the class-conflict in the whole development of things. The coming of the modern idea of progress greatly increased the disposition to look for deeper movements underlying the whole human drama. Whereas history had once been written as though it involved mere acts of will on the part of men and gods—acts of will taking place in the free air—there emerged the view that human beings are involved in processes, entangled in systems of conditioning circumstance. Whereas one's first impulse is to blame entirely the wills of a few people for the outbreak of the First World War of 1914, Prof. Temperley pointed out that one must go back at least as far as Bismarck in 1871 for the origin of that War. From that earlier date sprang the tendencies and developed the predicaments which set the terms for human action later. Over the course of the centuries the actual writing of history has changed its character, therefore, and its texture is no longer that of the mere story—the story of men doing just this and then that. What we call historical narrative in a man like Ranke or even Macaulay has a more analytical quality—the story wrapped up in expositions of processes and conditioning circumstance.

Furthermore, from the quasi-scientific use of the kind of data that the historian establishes there sprang a sort of political science, but later also political economy, various types of social study and other specializations like military strategy. They became autonomous and separated themselves from history; and in the course of time some of them were able to emerge as rivals to it. They have occasionally tried to make the return journey—their results are fed back into history and they may end by trying to secure dominion over it. We may be told that, on the last analysis, it is the study of the economic substructure of history that really matters. In the twentieth century—and not least in the United States—the relations between history and the social sciences have formed a crucial issue, for some have wanted to see history interpreted as really a branch of social science. On the other hand, the question might arise as to whether, after all the associated kinds of science have been

abstracted from it, there is anything left for the residual study—mere history.

We can see, therefore, how the memory of the human race has tended to acquire a certain form and organization. In general, the study of the past has affected at different levels our consciousness of life in time, and our feeling for the processes of time. It alters our vision of the present day, just as a piece of landscape must look different when the observer has the eye of a geologist. It affects our everyday habits of mind: and somebody has said that in the nineteenth century all thought ran to history—a fact very noticeable in politics, theology, philosophy and even natural science. Between this last and the study of history there have been interesting interactions, particularly at the birth of rationalism in early Greece and after the scientific revolution of the seventeenth century. From the eighteenth century even the scientists were showing a consciousness of time, as though the ultimate objective was to lay out the whole story of the physical universe. It should be remembered that, though we think of the historian as recovering the truth about the past, he is often revealing things never previously known to any man. We no longer hold the view (which until comparatively recently was sufficient for our predecessors) that somebody in the past always knew the truth about what had happened, and all that was necessary was to find this man. In the crisis of July 1914, every Foreign Office in Europe would have internal knowledge of only its own policy and its own reactions to the conduct of other Powers. The historian, using the papers of all the Foreign Offices concerned, can reach a kind of knowledge not possessed by any of the statesmen of the time. He can therefore give a higher organization to the whole story.

It is proper, moreover, that history should hold its ground as a thing possessing its own function and nature. Those who try to show from psychoanalysis what 'must' have happened may be liable to contradiction by new documentary evidence. Events are now always historically established if the case in their favour depends on some economic theory that is fashionable at the moment. There is need for a form of study that, in a sense, keeps close to earth, merely establishing what it was that

actually 'happened'. The need is all the greater, and the point becomes fundamental if we remember how much, in the workings of time, must still depend on the wills of human beings. We cannot exempt the men of July 1914 from all responsibility or pretend that everything was predetermined, the present simply the direct product of the past. Between the past and the future there always lie the decisions that human beings make in the living present. Because these can never be simply inferred, we must go to the evidence for them, and history must remain an empirical study.

Men may be entangled in a network of conditioning circumstance, but it is live men who are so entangled—men liable to make one decision at breakfast-time and a different one at dinner-time. It is important not to lose sight of these live human beings and not to eliminate their role by saying that they are mere products of their age. They are individual fountains of life and action, and all the factors that play on their minds are churned and recombined inside each of them, so that we can still never quite predict their action. Sometimes the historical processes which seem to paralyse their activity can bring a colossal leverage to the force that a single one of them exerts. At the same time, the view that recognizes this importance of the personality in the machinery of time must always allow a similar force to the operation of contingency. A short story may tell about hundreds of tiny actions, but one single coincidence among these may transform the entire development. Once again, we require, not merely a science of general laws, but an empirical study of detailed happenings, and a search for the ones that are pivotal. There is something in history to which justice cannot be done save by the kind of narrative in which we do not quite know what is going to happen next. It is true, then, that we need to study all that system of necessity which conditions human action, and interpretations of history tend to be commentaries on just that system. But we examine it rather to increase our control—we learn about it so that we may know better where our freedom lies. Because history so involves the awareness of this play of personality, it may be the safeguard for humanism in a technological civilization.

MAN-MADE LAKES

MAN-MADE lakes are coming to occupy a substantial area of former land. In Africa, for example, the 1,700 square miles of Lake Kariba on the Zambesi, the 3,200 square miles of Lake Volta in Ghana, the 1,800 square miles of Lake Nasser on the Nile, and the 500-square-mile lake due to form behind the Niger River dam at Kamji, will flood more than 7,000 square miles, and some 200,000 people are having to be resettled from the flooded areas.

The magnitude of these lakes demands that the fullest use be made of them. In addition to hydroelectric power, for which most of the dams are primarily constructed, their creation provides innumerable new opportunities, for irrigated farming, for fisheries development to supply much-needed protein, for transport, for the creation of nature reserves, National Parks and tourism. Some of the lakes are probably large enough to affect the local climate. The resettlement of people provides exceptional opportunities for inducing social and economic change, and for improving health. But to achieve all these things, each new lake must be considered as part of an integrated lake-basin development programme, and multi-disciplinary research is essential. Soil and vegetation surveys should be carried out to find suitable agricultural and for the displaced people. Biologists should be

concerned with problems of flooding, bush clearing, weed control and fishery development; anthropologists and sociologists with resettlement. Geographers and archaeologists and many others should come together with the engineers and hydrologists.

The United Kingdom also has its problems of man-made lakes, essential in a civilization whose demands for water increase at 4–5 per cent per annum. The old idea of a reservoir for water-supply only is giving way, under pressure, to the new idea of multi-purpose use, including recreation. Moreover, new lakes may encroach on the sea as well as on the land. Reclamation of estuaries, for freshwater supply as well as for agricultural land, has long been carried out in Holland, and the feasibility of doing something similar in Britain is now being considered in relation to Morecambe Bay and the Solway Firth. The Wash and the Thames have been suggested as other possibilities; while in Hong Kong an arm of the sea is to become a freshwater reservoir very soon.

The integrated investigation of such man-made lakes is comparatively new, and information is widely scattered. Therefore the successful symposium organized by the Institute of Biology during September 30–October 1 on this subject was very welcome. The meetings, which were held in the Royal Geographical Society hall, were attended

by about 200 delegates, including biologists, hydrologists, engineers and sociologists. It was a little surprising that there were present very few geographers, though they might have been expected to be specially attracted by this synthesis. The representation of disciplines stimulated lively discussions at each of the four sessions. As the study of man-made lakes is still in the data-gathering stage, each new lake is helped by the information derived from its predecessors, which adds to the importance of collating information as soon as it is available.

The first day was devoted to man-made lakes in the tropics; the second to those of the temperate zone. In each case the morning session was concerned primarily with aspects of the natural history of such lakes, and the afternoon sessions with problems arising from making and using them. As all the papers had been circulated before the meeting, contributors spoke briefly, summarizing their papers, adding up-to-date points, and illustrating them with photographs and slides. This allowed the maximum time for discussion.

The meeting was opened by Dr. Barton Worthington, scientific director of the International Biological Programme, who, as chairman of the first session, gave an introductory survey of the major schemes in progress and prospect in the tropics. He emphasized the beneficial influences of the great natural lakes of tropical Africa on those countries which are lucky enough to possess them, and pointed to the advantages of planning the new man-made lakes in such a way that they would bring similar benefits. Some biological research on the productivity of these lakes is already being done under the aegis of the International Biological Programme which has an integrated plan for expanded research. Next, followed papers on the hydrology and fisheries of Lake Kariba by D. Harding, formerly of the Zambian Fisheries Department; on the biological investigations in progress on the Volta Lake by Prof. D. W. Ewer, University of Ghana; and on the Brokopondo research project in Surinam, another 500-square-mile lake formed by closing the Suriname River dam in February, 1964, by Dr. P. Leentvaar. From data given in these three papers, a pattern emerged, of aquatic deoxygenation after the dams are closed and of the invasion of the new lakes by floating plants. At Kariba, there was also a huge burst of fish production. Supplementary data were provided on the hydrology and zooplankton of the artificial lakes on the Nile, such as the Jebel Aulia reservoir, by Dr. J. Rzoska and Dr. J. F. Talling, and by Dr. D. J. Lewis on the problems of mosquitoes and malaria which were associated with their formation. The research in progress on the River Niger in anticipation of the lake to be formed above the Kainji dam was described by Dr. E. White, who had just returned after a survey conducted by fourteen scientists drawn mainly from the Universities of Liverpool and Ife.

In Africa, where the man-made lakes are all impounded from large rivers, they have a much larger through-put of water than the natural lakes. The Nile impoundments at Sennar and Roseires fill and empty every year; Kariba with its much greater volume took four and a half years to fill. But R. S. A. Beauchamp mentioned that Lake Tanganyika, if emptied, would take 1,500 years to fill from its inflows. These differences are reflected in the water chemistry of the 'young' water of the new lakes and the 'old', almost fossilized, water of the old lakes. As a contrast, Dr. C. M. Yonge spoke of the problems of turning an arm of the sea into fresh water in Hong Kong, with an abrupt change from salt water to fresh water. A lively discussion was stimulated by the question how much notice and research are needed for biologists and hydrologists to make useful prognostications of happenings in the stored water, for engineers to take the requisite remedial measures.

The meeting was fortunate in having Sir Robert Jackson, special adviser to the United Nations Special

Fund, as its chairman for the afternoon session concerned with the problems arising from making lakes in the tropics, for Sir Robert has been intimately involved with the Volta and other schemes for a long time. Two papers presented were on the establishment of fisheries in the new lakes, by P. B. N. Jackson of Jinja and the Food and Agriculture Organization, and by Dr. L. Joeris of the Food and Agriculture Organization Kariba Research Institute; Dr. E. C. S. Little of the Weed Research Organization spoke on the invasion of man-made lakes by plants, and Dr. B. B. Waddy of the London School of Hygiene and Tropical Medicine on medical problems arising from making lakes in the tropics. The social and economic problems of the indigenous peoples were discussed by Dr. T. Scudder of the University of California, who had studied the displaced Tonga at Kariba and been concerned with the plans for the resettlement of the Nubians from Lake Nasser and of those people to be displaced by the Kainji Lake. Additional contributions came from Prof. W. E. Kershaw on the *Simulium* problems at Kainji, from Dr. C. F. Hickling on weed control and barriers to fish migration. Dr. C. G. L. Bertram commented on the idea of using manatees to control aquatic weeds.

Sir Robert Jackson pointed out that the budgets of these large schemes may be limited by outside factors, in the case of Volta by the price of aluminium. The budgets of the consultants have to be framed to fit and this may mean that not enough money can be allowed for research, for resettlement or for clearing bush. The Government concerned will then have to try and find other funds, and until the research is done it is difficult to convince Governments of such needs. In developing countries the sheer weight of problems needing solution, falling perhaps on relatively few trained personnel, may lead to serious delays.

Clearing the bush from land to be flooded is costly. How much clearing is really necessary to enable the lakes to be profitably fished? Experience has shown that the main species of fish in the man-made lakes of Africa, *Tilapia* and *Labeo* in particular, can best be caught in bottom-set gillnets which are impossible to use unless the flooded land has been cleared. Furthermore, rotting vegetation, if the bush is not cleared, causes extensive de-oxygenation, so that the bottom waters become barren of fish and other life, and strongly sulphurated waters affect the turbines. How long these situations will persist depends on the shape, size and position of the lake in relation to temperature changes and prevailing winds. Lake Kariba, lying more than 1,500 ft. above sea-level and some distance from the equator, has a seasonal overturn which carries oxygenated water to the bottom. Lakes Volta and Brokopondo, lying nearer the equator and at a lower altitude, have less marked seasonal changes, and de-oxygenated bottom waters have persisted throughout the year. But, as the last-mentioned two lakes only started to fill in spring 1964, it is too soon to say how they will continue to behave. Lakes Kariba and Volta are both in savanna bush country. At Kariba a sizeable sum was spent on clearing, and a fishery developed almost immediately. On the Volta site very little clearing was done; there is as yet no significant fishery. Brokopondo lake lies in high rain forest and no clearing was attempted. Lake Nasser lies in desert so the problem of clearing does not arise. But for the Niger lake, which is to be filled in 1967 and which lies in savanna bush, the question of how much bush needs to be cleared is now an urgent issue.

Uncleared bush also aggravates the weed problem. Dramatic photographs of Kariba showed the mats of floating weed, *Salvinia auriculata* and *Pistia stratiotes*, accumulated around the tops of submerged trees. Such weed impedes access to the shore, interferes with lake transport and fishery development, and provides a

stratum on which larger sudd-forming vegetation is able to establish itself. But in time the Kariba weed has died down, and is now confined to bays and inlets. Volta Lake, where an anxious watch and chemical sprayings of possible foci have been used to prevent weed growth, was at first free of weed, but it now also has the problem of *Pistia* accumulation. In Brokopondo in South America the water hyacinth, *Eichhornia crassipes*, has invaded large areas of the lake, and a water fern, *Ceratopteris thalictroides*, has established itself also. The Congo and Nile are among the many waters to have suffered from extensive *Eichhornia* outbreaks, and the high cost of weed control, necessary to keep channels open for navigation and to stop the weed mats blocking sluices and turbines, makes any research which is designed to prevent outbreaks well worth while. There is a further important problem concerning the influencing of floating vegetation on the hydrology, arising from the evidence that transpiration from the plants is higher than evaporation from an equivalent area of free water surface.

The great new tropical lakes around which whole populations have to be resettled provide a wide range of human as well as biological problems. Health measures are essential in connexion both with dam building and resettlement. The labour force is relatively easy to care for, but there is likely to be a most unhealthy focus of concentrated humanity with heavy parasite loads at some boom-village near the dam site, composed of those who came there hoping for jobs but were found unfit.

Several illnesses associated with water require study. Oncocerciasis carried by *Simulium*, the larvae of which live in running water, may become less of a problem as the river becomes a lake, but malaria and schistosomiasis are both associated with still water and may present greater dangers. There are also disease hazards when people are moved to their new homes. The mental stress of adopting a new way of life away from familiar and sometimes sacred things like graves of ancestors and shrines is not the least of the problems. Land has to be cleared for cultivation in the new areas, and after moving, the people have to await the rains before the new gardens can be planted. Anthropological and archaeological studies in the lake area before, during and after flooding may help to understand and mitigate such problems.

Sociologists have found that the removal period provides opportunities which should not be missed. The resettled people tend initially to be in a state of cultural shock, and at this time are receptive to new ideas; for example, new fishing methods can then be introduced. But in a few years' time a period of resistance to new ideas tends to set in, so the opportunity is lost if not seized at once. Resettlement calls for much advance planning, land surveys to determine suitable agricultural land and alternative means of employment if land is short, as well as building new villages. If the fishery is to be fully developed, fishing schools will have to be established to teach the people to use the new types of gear necessary to crop a lake. Moreover, the best gear must be decided and made available, including boats with engines to cover the larger area of water. Experience shows that not enough time and resources are generally allowed for these complicated operations.

The Dutch have unrivalled experience in impounding waters from the sea, and the meeting was fortunate in having Dr. K. F. Vass, Director of the Hydrobiological Institute, Yerseke, Holland, to speak on lakes in Dutch reclamation schemes. This contribution opened the discussion on the natural history of man-made lakes in the temperate zone under the chairmanship of Dr. J. W. G. Lund. Papers followed on the biological implications of the proposed barrages across Morecambe Bay and the Solway Firth by Mr. H. C. Gilson, of the Freshwater Biological Association, and on the hydroelectric schemes in Scotland, especially their effects on the salmonid fisheries, by Dr. K. A. Pyefinch, from Pitlochry.

In addition to water supply, an area such as Morecambe Bay impounded by a barrage could provide water for cooling power stations, a road to the north-west, and recreational facilities for sailing, fishing, etc. Additional information was contributed on weed and plankton growth in Loch Leven by Mr. N. C. Morgan, as this lake was thought to be one which the impounded Morecambe Bay would come to resemble. Mr. Gilson predicted that Morecambe Bay could support a good trout fishery, but management would be necessary because it would tend to become rich in pike and eels. The problems of the descent of salmon smolts to the sea could perhaps be overcome by trapping them in fresh water, acclimatizing them to brackish water and then releasing them in the sea.

The behaviour of salmonids, which support valuable sport fisheries, and the survival of smolts as they pass through turbines, were discussed with reference to the Scottish experience of the use of louvres to deflect smolts from turbines. Experience showed that biologists need extensive knowledge of the engineering details of such schemes and the physiology and behaviour of the fish to give proper advice.

The extensive investigations carried out in the U.S.S.R. on man-made lakes, which were described by Dr. J. Rzoska, have been made mainly in the temperate zone. The pattern common to most new lakes is of the original stock of river food being demolished and fish spawning grounds disturbed in the first year, often followed by a period of accelerated fish growth and increased yields associated with eutropication and leaching of soils. It takes at least 10 years before the zooplankton becomes stabilized, and up to 18 years before the benthic fauna settles down. The fish fauna changes enormously, often in ways not foreseen, so that it may take in all more than 20 years before the new lake is stabilized. Even then it may be found that some ecological niches are not filled. Where the emphasis is on the production of fish for food, should gaps in the food chain be closed by introductions of benthic fauna, or of fish to utilize the productivity of the zooplankton? Russian experience has also shown how reservoirs create conditions for the spread of animals: the Caspian fauna is spreading northwards and the northern fauna southwards. The study of man-made lakes is considered so important in the U.S.S.R. that a new institute and a journal for publication of results have been especially established.

At the final session, under the chairmanship of Prof. O. E. Lowenstein, other problems associated with the use of man-made lakes in the temperate zone were considered. Papers were presented on engineering and economic aspects of large-scale water supply by F. Law of the Fylde Water Board; on maintaining the safety and quality of water supplies by Dr. G. U. Houghton of the South Essex Waterworks Co.; and on the multi-purpose use of reservoirs by L. H. Brown, Mid-Northamptonshire Water Board.

Mr. Law compared the costs of water storage by conventional means (some £400 per million gallons) with estimated costs for storage behind a sea barrier, which he thought would be about eight times as great. Differences in water supply in the north-west and south-east of England were commented on. In the north-west there is more rain, but in the south-east larger storage reservoirs are necessary to guard against a series of dry years. In the north-west the water is used once only, but in the south-east it may be used several times, being circulated through sewage works, back into the rivers and then used again farther down-stream before going to sea. The health aspects and types of filters and treatment plant were described by Dr. Houghton. Would it be cheaper for people to have their own filters and use untreated water for purposes such as washing cars? And how does metering affect water costs? Another contributor to the discussion pointed out that desalinization

costs were falling, whereas conventional storage costs were rising.

The final paper, on experience gained in the United States in recreational use of artificial waters, was given by R. H. Stroud of the Sport Fishing Institute, Washington, D.C. After considering fishery management in reservoirs, Mr. Stroud ended with a very useful commentary on some of the work described in earlier papers, including the tropical work. A main question in the discussion which followed was the extent to which water supply can be considered in isolation from other uses of reservoirs. With the development of motor-ways opening up the country, there is increased demand for access to reservoirs for recreational purposes. Since the water is treated anyway, there may be little harm in allowing access to reservoirs for fishing, sailing and bird watching, though access must be controlled to prevent abuse. Some recreational interests may conflict: reservoirs which are wild fowl reserves would suffer if opened to the general public, and water-skiing is not popular with anglers. Experience in the United States strongly supports the multi-purpose use of reservoirs. In the United States 95 per cent of the waters are publicly owned, in contrast with many waters in private hands in the United Kingdom, and the surprisingly high figure of 40 per cent of the commercial food fish eaten in the United States is caught by anglers.

The information required from biologists by engineers was discussed. It was pointed out that engineers have to reach decisions whether or not all the facts are known; therefore, biologists should, perhaps, be more concerned with orders of magnitude than with seeking answers in too precise quantitative terms, when trying to assist engineers. Biologists need a data-gathering stage, and experience suggests that five or six years is necessary if the biologist is to advise soundly on large and complex schemes. Each study helps later investigations, and there is a great need to record results fully and to co-ordinate the experience now gleaned from the various projects. Turning a river into a lake, as was pointed out by F. T. K. Pentelov, is bound to lead to an unstable situation. The period needed to attain stability in each case can, at present, only be guessed at, but will be a function of the generation time of the plants and animals surviving or introduced. Thus it is probably longer in higher latitudes than in the tropics. Some problems arising, such as weed growth, may solve themselves, but there is a need to define the long-term and persistent problems before tackling them. A general pattern which emerges is that there is likely to be very high productivity in the first year or so after the lake fills, due to leaching of the soils and decomposition of drowned plant and animal matter. Then there may be a rather abrupt fall in productivity, followed by a period of many years before the lake stabilizes. Estimates from experience gained in the U.S.S.R. suggest at least 6–10 years in lakes below latitude 50° N. and 25–30 years in higher latitudes.

At every session discussions were vigorous and many questions remained unasked and unanswered. Since biologists have to predict results, such as the yields of fish likely from certain bodies of water, before the research

is done, in order to justify and obtain funds for research, one would have liked more information on how actual yields have borne out predictions—and on the reasons for any major discrepancies. Moreover, there is still need for data from natural lakes which guide to predictions for man-made lakes. There was no mention of the fact that Lake Victoria, nearly the size of Ireland, is now the largest reservoir in the world by reason of the Owen Falls dam at its outlet. One would have liked, too, to have heard what happens to the accumulative chemical pesticides when water is purified for re-circulation. As Mr. Stroud pointed out, the enormous amount of work on the 1,200 reservoirs in the United States was scarcely considered; these cover a wide geographical range, and data from them, now being processed by computer, might help predictions in other areas.

The symposium brought out clearly the opportunities presented by the making of new lakes if the problems are tackled in a multi-disciplinary manner. There is always a need for a strong focal point to bring the biologists and sociologists into touch with the engineers at an early stage. The time factor is vital: not only must the research start early enough, but it is also necessary to beware of the hiatus which often occurs between the initial scientific work on a scheme and its implementation. This gap may last years while finance is being sought and it often causes a loss of impetus in the scientific programme. As a result a hastily organized crash programme becomes necessary.

In addition to the formal papers presented and discussed, this symposium was particularly valuable in bringing together representatives of varied disciplines. Many of those attending had never before had the opportunity to meet their colleagues working on similar problems in other parts of the world. Thanks are due to the Institute of Biology for organizing the meeting, and to the Royal Society, the Ford Foundation and the American Conservation Association, who provided travel funds to enable some of the overseas delegates to attend.

The desire was expressed, especially by the tropical workers, for a meeting a few years hence, to bring the working scientists and engineers together again, preferably on one of the new great lakes in the tropics. Air fares may seem expensive, but exchange of experience and the proper planning of these great developments can prove a sound investment. Another follow-up to the symposium may be expected in the field of information and bibliography. Stimulated by the special interest of ICSU in the subject, the African Science Board of the National Academy of Sciences, Washington, D.C., has arranged for the preparation of a selected guide to the literature on man-made lakes, and copies were available at the symposium. Another bibliography, on reservoir fishery biology in North America, was issued this year by the Department of the Interior, Washington, D.C. Perhaps there is a case now for establishing a small bureau of scientific information on all aspects of man-made lakes, so that data can be collected and distributed without the inevitable delays associated with the normal routine of publication.

ROSEMARY L. McCONNELL
E. B. WORTHINGTON

OBITUARIES

Prof. Jocelyn Patterson

PROF. JOCELYN PATTERSON, head of chemical pathology at Charing Cross Hospital Medical School, University of London, since 1948, died suddenly at his home in Chorley Wood on September 6 within a few days of his sixty-fifth birthday.

He was educated at Armstrong College, University of Durham, and graduated with first-class honours in

chemistry in 1920; the following year he was awarded a Master's degree. His first research work was on the halogenation of unsaturated hydrocarbons and on organic sulphur compounds. Moving to St. Salvator's College, University of St. Andrews, he gained his Ph.D. in 1923, and worked under the direction of the late principal, Sir James Irvine, much of this time acting as the latter's private research assistant. Here he gained wide experience

in the chemistry of carbohydrates, especially with regard to fructose and its derivatives.

In January 1924 Charing Cross Hospital and Medical School were fortunate and wise to secure his services as their first biochemist and lecturer in chemical pathology. His research activities were chiefly on quantitative aspects of chemical pathology.

In 1938, collaborating with H. W. C. Vines (later professor of pathology at Charing Cross Hospital) and others, he assisted in writing *The Adrenal Cortex and Intersexuality*, and in 1952 he contributed a section to *Recent Advances in Chemical Pathology*. Apart from his main interests, many papers published by other Charing Cross staff acknowledge the assistance he gave to them in their work; indeed, his wise and balanced judgement was widely sought and appreciated by all who came into contact with him.

After the Second World War in 1947, when the pre-clinical school of Charing Cross was re-established, Prof. Patterson became responsible for the teaching not only of chemical pathology but also of biochemistry. In 1948 the University of London conferred on him the title of professor of chemical pathology. Just previous to his death the University of London conferred on him the title of emeritus professor. He served as vice-dean of the Medical School from 1954 until 1957, served on the School Council, and for many years he was on the Board of Governors of the Hospital. He was a member of the Boards of Studies in Biochemistry and in Pathology and also of the Board of Pre-Clinical Studies of the University of London. After Charing Cross Hospital became associated (in 1959) with the West London and Fulham Hospitals, Prof. Patterson took on the additional responsibility of supervising their chemical laboratories.

Prof. Patterson's hobbies included gardening, and at his home in Chorley Wood he had a beautiful well-kept garden.

In 1926 he married Kathleen (*née* Thompson), who survives him. To her and his son we extend our sympathy.

W. J. HAMILTON

Prof. Wilfred Merchant

PROF. WILFRED MERCHANT, professor of structural engineering in the Faculty of Technology, University of Manchester, since 1957, died on October 12 at the age of fifty-three after a long illness. He was educated at Manchester Grammar School and graduated with first-class honours in engineering science at Oxford in 1933. He then spent a number of years with a large firm of structural engineers.

He held a Commonwealth Fellowship at the Massachusetts Institute of Technology and obtained the degree of M.S. in 1939 with a thesis in soil mechanics. This work was the first rational advance of the general theory of consolidation of clay since its formulation in 1923, and it has recently been recognized that modern treatments of the subject are mathematically equivalent to that in Merchant's 1939 thesis.

During the Second World War, Prof. Merchant was employed by Metropolitan Vickers, Ltd., on the design of jet engines. He made major contributions to the aerodynamic theory of flow through compressor blading. There was very little knowledge or experience of axial flow compressors at that time and his contributions played an important part in the design of jet engines.

Prof. Merchant joined the staff of the Manchester College of Science and Technology, Faculty of Technology in the University of Manchester, in 1946, and was appointed reader in applied mechanics in 1951. After he joined the College his main interests were in the prediction of the failure load of structures taking account of the interaction of plasticity and stability. His intuition led him to propose an interaction formula which is now accepted and known by his name in the literature of the

subject. During the past few years he developed computer techniques to carry out the erection calculations for the new Forth and Severn suspension bridges.

He was a member of the Institution of Structural Engineers, a member of the Institution of Civil Engineers and an associate member of the Institution of Mechanical Engineers and of the American Society of Civil Engineers. He served his professional institutions in many ways and was chairman of the Lancashire and Cheshire branch of the Institution of Structural Engineers during 1960-61.

As a teacher he always found time to discuss problems individually with his students. His advice and guidance both to his students and to his colleagues were of great value. His contributions in three major branches of engineering are significant of his wide interests and keen analytical mind.

He leaves a wife, a son and a daughter. S. S. GILL

Dr. Paul Müller

PAUL MÜLLER, who was awarded the 1948 Nobel Prize for Physiology and Medicine, died in Basle on October 13, 1965, after a short illness.

Paul Müller was born on January 12, 1899, in Olten. His father, who was on the staff of the Swiss Railways (SBB), moved soon afterwards to Basle, and Basle became his home. There, after a spell as laboratory technician, he completed his studies at what was then the Obere Realschule (Modern High School) and then read chemistry at the University under Profs. Fichter and Rupe. In 1925 he took his doctorate with the highest honours, with a thesis on "The Chemical and Electrochemical Oxidation of Asymmetrical *m*-Xylidene and its Mono- and Di-methyl Derivatives". In the same year he joined Geigy as a research chemist, and he stayed with the firm for the rest of his life.

At first he worked on tanning, and developed a number of new synthetic tans. The problem of the preservation and disinfection of animal skins soon turned his attention to biology; and from 1935 he became more and more interested in pest control, a field with which organic chemists at that time had little concern. In the difficult years of the Second World War, when the battle for production was on, he developed and made available to Swiss farmers a mercury-free seed dressing. While still engaged on this development work his interest was turning to insecticides, and with characteristic doggedness he tested large numbers of chemical compounds, at first without success. But in 1939 his perseverance, coupled with his acute perception and methodical approach to all his experimental work, led him to the discovery of the insecticidal properties of dichloro-diphenyl trichloroethane, the active ingredient of DDT, which he developed for practical use. His achievement was to have discovered, at a critical time in the War, an insecticide with a contact and persistent action far and away superior to any other known product. His discovery was used both during and immediately after the War to protect millions of service-men and civilian populations in all countries against epidemic diseases. Apart from their use in hygiene and agriculture, DDT insecticides are still extensively used to-day with success in many parts of the world against the *Anopheles* mosquito, the carrier of malaria. The significance of this great discovery was fittingly acknowledged by the award of the Nobel Prize for Physiology and Medicine in 1948.

In 1963 Müller received an honorary doctorate in the Faculty of Medicine at the University of Thessalonika, in recognition of the beneficial effect of DDT products in the Mediterranean area. He also became an honorary member of the Swiss Nature Research Society and of the Paris Society of Industrial Chemistry.

For all these many distinctions, Paul Müller remained what he had always been: a modest man, outwardly reserved, but with a passionate devotion to science. Even

as deputy head of pest control research at Geigy, he preferred above all else the work of a research chemist. After his retirement in 1961 he continued to devote his energy and enthusiasm to work in his private laboratory at his home in Oberwil, near Basle. He found relaxation

in his beloved countryside, in the Jura mountains and the Alps, and in family life. By his death, Basle and its chemical industry, and indeed the world of science, have lost a scientist whose personality and attainments will not soon be forgotten.

NEWS and VIEWS

The Royal Society:

PROF. P. M. S. BLACKETT, emeritus professor of physics, University of London, Senior Research Fellow, Imperial College of Science and Technology, London, and part-time scientific adviser to the Ministry of Technology, has been elected president of the Royal Society in succession to Lord Florey. The new physical secretary is Prof. M. J. Lighthill, Royal Society research professor at the Imperial College of Science and Technology. The new foreign secretary is Prof. H. W. Thompson, professor of chemistry in the Physical Chemistry Laboratory, Oxford. The officers re-elected for the ensuing year were: *Treasurer*, Lord Fleck, formerly chairman of Imperial Chemical Industries, Ltd.; *Biological Secretary*, Prof. A. A. Miles, director of the Lister Institute and professor of experimental pathology in the University of London. Other members of Council elected (or re-elected, marked *) were: Prof. M. S. Bartlett, professor of statistics at University College, London; *Prof. D. H. R. Barton, professor of organic chemistry at the Imperial College of Science and Technology, London; Lord Brain of Eynsham, consulting neurologist to the London Hospital and consulting physician to Maida Vale Hospital; *Dr. F. S. Dainton, vice-chancellor of the University of Nottingham and honorary director of the Cookridge High Energy Radiation Research Centre, University of Leeds; *Prof. K. C. Dunham, professor of geology in the University of Durham; *Prof. G. W. Harris, Dr. Lee's professor of anatomy at the University of Oxford; Dr. S. G. Hooker, technical director (aero), Bristol Siddeley Engines, Ltd.; *Prof. W. O. James, professor of botany at the Imperial College of Science and Technology, London; Dr. J. C. Kendrew, deputy chairman of the Medical Research Council Laboratory of Molecular Biology, Cambridge; Dr. R. D. Keynes, director of the Institute of Animal Physiology, Babraham, Cambridge; *Sir Hans Krebs, Whitley professor of biochemistry at the University of Oxford; *Dr. N. Kurti, reader in physics, University of Oxford, and Senior Research Fellow, Brasenose College; *Dr. K. Mather, vice-chancellor of the University of Southampton; Prof. P. T. Matthews, professor of theoretical physics at the Imperial College of Science and Technology, London; Dr. L. Rotherham, member for research, Central Electricity Generating Board; Sir Solly Zuckerman, chief scientific adviser to the Secretary of State for Defence, scientific adviser, Cabinet Office, and Sands Cox professor of anatomy in the University of Birmingham.

Prof. P. M. S. Blackett, C.H., P.R.S.

THE attainment of the highest scientific honour in the land crowns a distinguished career of more than forty years. Patrick Maynard Stuart Blackett has received many honours. A range of physical research, particularly an intensive study of cosmic rays by the cloud chamber method, led to his election as Fellow of the Royal Society in 1933, the award of a Royal Society Medal in 1940 and a Nobel Prize for Physics in 1948. He has three times served on the Council of the Royal Society—during 1940–42, during 1944–46, when he held the office of vice-

Officers

president for a year, and during 1963–65. In 1946 he was awarded the American Medal of Merit for his work in operational research, and 10 years later he was again honoured by the Royal Society, receiving the Copley Medal for his work in the fields of cosmic rays and palaeomagnetism.

Blackett began his scientific career at Cambridge in the great days of the late Lord Rutherford. He had achieved an international reputation before he was thirty—a more remarkable achievement in that he started late, for he began life as a sailor. Born on November 18, 1897, Blackett was educated at the Royal Naval Colleges at Osborne and Dartmouth. He served in the Royal Navy throughout the First World War, taking part in the battles of Jutland and the Falkland Islands. His keen interest in science led him after the War to Cambridge, where he studied physics under Prof. Rutherford (as he then was). Blackett graduated in 1921, and 2 years later was made a Fellow of King's College. He worked in the Cavendish Laboratory from 1921 until 1933 when he became professor of physics at Birkbeck College. In 1937 he went to the University of Manchester as Langworthy professor of physics, succeeding Sir Lawrence Bragg who himself had succeeded Rutherford. During his 16 years at Manchester, Blackett presided over and greatly expanded a department which already had a fine tradition. This achievement was repeated by Blackett at the Imperial College of Science and Technology, which he joined in 1953 as professor of physics and head of the physics department, and was responsible for the planning and supervision of the College's fine new Physics Building which was opened in 1960. Perhaps Blackett's most important contribution to the growth of British academic physics during this period was his persuasive support for the College's campaign for a very substantial increase in the number of professors. This trend away from the old European concept of one professor towards the multi-professorial pattern forming a department with a broad field of study is now widely accepted. Blackett has served the Imperial College in many capacities. He was dean of the Royal College of Science from 1954 until 1960 and pro-rector from 1961 until 1963. On his retirement in September 1965, he was appointed a Senior Research Fellow and will continue to have a research laboratory in the physics department.

Blackett and those working with him have made significant contributions to three main fields of physical discovery: the interaction with matter of fast particles from radioactive sources, the nature of the particles in the cosmic rays, and the magnetism of the Earth. During 1921–31 he was chiefly occupied with the development and operation of automatic Wilson cloud chambers and their application to the precise measurement of the parameters involved in collisions between α -particles and atomic nuclei. He photographed for the first time the disintegration of a nucleus. From 1931 onwards he applied and extended the cloud-chamber technique to the study of the collisions involved in the cosmic rays, establishing with Occhialini the existence of showers of nearly equal numbers of positive and negative electrons. From 1947 onwards, Blackett revived interest in the old

theories of Schuster and others of the possibility of a 'fundamental' connexion between the angular momentum of a large rotating body such as the Earth, and its magnetic field. Further astronomical and geophysical evidence made the theory untenable. As a by-product, a special magnetometer was designed for this work and has been widely used in the rapidly growing subject of palaeomagnetism. Out of this work, which is being energetically pursued in many countries, is emerging the beginnings of a history of both the wandering of the continents and of the Earth's magnetic field. During recent years Blackett has directed a small group working on palaeomagnetic problems, doing much of the experimental research himself.

Blackett has made many valuable contributions in the wider field of British science. Always an enthusiastic supporter of and advocate for the applied sciences he became an active member of the National Research and Development Corporation in 1949, and is now deputy chairman of the Advisory Council in the Ministry of Technology. From 1956 until 1960 he was a member of the council of the Department of Scientific and Industrial Research during a period when a phenomenal growth occurred in grants to university departments for scientific and technological research. In January 1965 he was appointed by the Secretary of State for Education and Science to the Council for Scientific Policy. Blackett has played an active part in many aspects of the impact of science on public affairs. His contributions to the study of problems of disarmament are well known, as also is his interest in scientific and technological aid to emergent countries—the subject of his Presidential Address to the British Association for the Advancement of Science in 1957.

Biochemistry and Organic Chemistry at Charing Cross Hospital Medical School : Prof. A. N. Davison

DR. A. N. DAVISON has been appointed to succeed the late Prof. J. Patterson (see p. 1042 of this issue of *Nature*) in the chair of biochemistry and organic chemistry at Charing Cross Hospital Medical School. Dr. Davison was born in 1925 and was educated at Westcliff High School, University College, Nottingham, and Birkbeck College, London. He holds the following degrees of London University: B.Pharm. (1946), B.Sc. (1950), Ph.D. (1954) and D.Sc. (1963). He served in the Royal Army Medical Corps from 1946 until 1948, and was afterwards appointed a group manager with Messrs. Potter and Clark, Ltd. In 1950 he joined the staff of the Medical Research Council Unit for Research in Toxicology to work on cholinesterase inhibitors. A year (1954–55) at the Sorbonne was followed by his appointment as biochemist to Roche Products, Ltd., and then (1957) by his becoming a member of the Medical Research Council external staff in pathology at Guy's Hospital Medical School. In 1960, Dr. Davison was appointed lecturer and then reader in the Biochemistry and Chemistry Department at Guy's Hospital Medical School. He is particularly well known for his work on the biochemistry of brain lipids and on aspects of brain metabolism generally. His demonstration (with the late Prof. G. Payling Wright and Dr. J. Dobbing) in 1958 of the persistence of radioactive cholesterol, once deposited in the brains of young animals, contradicted generally held biochemical opinion, which was dominated by Schoenheimer's conception of a dynamic equilibrium of constituents of the living body.

Science in Belgium

THE National Council for Scientific Policy, Belgium, has published a study of the scientific potential of Belgium in 1961. It covers the whole range of scientific activity in Belgium, including manpower, organization, institutions, equipment, financial resources and distribution (Conseil

National de la Politique Scientifique. *Inventaire du Potentiel Scientifique 1964 de la Belgique—Année 1961*. Pp. 303. Bruxelles: Conseil National de la Politique Scientifique, 1964). Of a total of 22,504 full-time scientific workers, 6,703 had university degrees and 2,451 diplomas or some higher technical qualification, the remaining 13,350 being technicians or other workers. These were distributed among 1,644 scientific units with an expenditure of 4,312 million francs, excluding that in the educational field, inter-university centres and learned societies; 810 units employing 3,623 of these with a university degree were in the educational sector; 204 (1,100) were in the public sector; 431 (1,437) in private enterprise; 57 (328) in research associations; 4 (143) in inter-university centres; and 84 (11) in learned societies. The expenditure in the public sector was 1,465 million francs; in private enterprise, 2,404 million francs; and in research associations, 400 million francs. Of the scientific units and persons with a university qualification, 1,284 and 5,433, respectively, were engaged in the exact sciences; biology (174 and 764), medicine (182 and 1,064), and technology (620 and 2,136) taking the most, with physics (99 and 604) and chemistry (85 and 496) coming next; 180 units and 821 of the qualified personnel were in the social sciences, but expenditure was only 264 million francs, compared with 3,902 million francs on the exact sciences. In the field of education, in 8.5 per cent of the scientific units employing 85.5 per cent of the staff, research was an important activity; in the public sector the corresponding figures were 71.6 per cent and 73.9 per cent; in private enterprise, 55.7 per cent and 86.6 per cent; and in research associations, 61.4 per cent and 71 per cent. 80 per cent of the scientific units and 88 per cent of qualified staff in the educational sector are in the four universities, and 56 per cent of this staff is in the faculties of science and medicine. Only 10 per cent of the private firms employed more than 1,000 people, but these firms employed 49 per cent of the university-qualified staff engaged in this sector. Almost half the scientific units and a little more than half the staff with a university degree are employed in the provinces of Brabant, Liège and East Flanders, with some 15 per cent of the scientific units, and corresponding proportions of qualified staff, but in the latter province some 85 per cent are employed in the educational sector. In the exact sciences, 25.9 per cent of the scientific units and 33.7 per cent of the qualified staff were engaged exclusively or mainly in fundamental research, and 62.1 per cent and 54.1 per cent, respectively, exclusively or mainly in applied research.

Training of Public Health Officials

UNDER the lengthy title *Special Courses for National Staff with Higher Administrative Responsibilities in the Health Services*, a report has been published by the World Health Organization (Technical Report Series, No. 311. Report of a WHO Study Group. Pp. 31. Geneva: World Health Organization; London: H.M.S.O., 1965. 2 Sw. francs; 3s. 6d.; 0.60 dollars). The document attempts to emphasize the need for well-informed public health officials and to outline the general principles underlying the training they require. The report points out that many public health administrators, whether medically qualified or not, are not conversant with the knowledge and techniques required for the efficient administration of public health services. In order to meet the pressing demand for competent health administrators, particularly in the developing countries, the World Health Organization Study Group has advocated the establishment of intensified two-month courses for health administrators with or without medical qualifications. Such courses, the report concludes, should be sponsored at Government level or by official health organizations. The content of such courses should cover three principal aspects of public health: (1) historical development and philosophical concepts;

(2) scientific and technical subjects involving the study of such matters as the implementation of public health programmes and the nature of environmental and social health problems; (3) administration. Under this last heading such topics as the evaluation of public health programmes and the economic aspects of health and disease would be considered. Full-time courses, fellowships, and seminars covering similar schemes of study are also advocated for personnel who are likely to be more suited to these forms of training. Details of the types of programmes in public health administration already adopted or advocated by universities in Yugoslavia, Canada and the United States, and by Government organizations in Mexico and India, are given in appendixes to the report.

South Australian Museum

THE annual report of the South Australian Museum for the year ended June 30, 1964, states that the most noteworthy aspect of the year's progress is the increased efficiency resulting from the appointment of the Museum's first information officer (South Australia. Report of the Museum Board, 1 July, 1963, to 30 June, 1964. Pp. 11. Adelaide: Government Printer, 1965). This has relieved the research staff of an immense volume of enquiries and is of special benefit to trainee-teachers and senior students. A registry of speech and sound collections has been prepared. This includes wax cylinders, acetate disks and tape-recordings of data on the Australian Aborigines. It has been of especial value to the Australian Institute of Aboriginal Studies. The staff has been active in assisting cognate organizations such as National Parks and Wild Life Reserves and the Flora and Fauna Advisory Committee of the Zoological Society. More than thirty major papers have been published by the staff during the period under review.

Pesticide-Wildlife Studies

SUMMARIES of Federal pesticide-wildlife investigations in the United States have been prepared from time to time. In 1963, in order to integrate Federal studies with those of other agencies, the United States Fish and Wildlife Service requested the co-operation of the Canadian Government and Provinces, each State, and the universities in listing and describing their pesticide-wildlife investigations. These investigations have been summarized, giving the identification of the State, Province, or university, research worker in charge, title and description of the work, and a brief abstract of findings and progress. The tabulation is alphabetical by States, and separately by Provinces, where the work was done or administered. Some of the projects may now have been terminated or may not be active. Much of the work is unpublished, but a list of addresses should facilitate direct communication with investigators. The survey was part of an international listing of research co-ordinated by the Committee on Ecological Effects of Chemical Controls of the International Union for the Conservation of Nature and Natural Resources, and prepared by John L. George, co-operator, Division of Wildlife Research, Bureau of Sport Fisheries and Wildlife. The international listing is arranged alphabetically by author under various subjects such as analytical techniques for chemicals, ecological effects on organisms of different major habitats or of captive animals, and vegetation control of chemicals (U.S. Department of the Interior: Fish and Wildlife Service. Circular No. 224: *Pesticide-Wildlife Studies by States, Provinces and Universities—An Annotated List of Investigations through 1964*. Pp. i+30. Washington, D.C.: Government Printing Office, 1965).

Laboratory Animals for Rheumatism Research

THE Nuffield Foundation, as part of its programme of research into possible underlying causes of rheumatic

disease, is anxious to intensify the search for naturally occurring forms of rheumatoid, or rheumatoid-like, lesions in animals suitable for laboratory investigation. A naturally occurring rheumatoid arthritis in monkeys, for example, would have important implications for the controlled study of the disease. The fact that no evidence—or very little—has so far been obtained that this affliction of man is shared by other primates may simply be due to the almost total preponderance of young animals among those which have been available for study. The Foundation would now like to extend the search to cover a reasonably large sample of older monkeys, and to submit to expert examination the hands and feet (to include wrist and ankle joints) of elderly monkeys, preferably of known age. Centres already concerned in primate investigations, in the laboratory or in the field, and where colonies of monkeys are maintained throughout their natural life span, would evidently be in the best position to help. Offers of assistance should be addressed to Mr. Brian Young, the Nuffield Foundation, Nuffield Lodge, Regent's Park, London, N.W.1, stating the numbers, species and age-groups of monkeys available for examination. In some cases it might be possible to arrange for on-the-spot X-radiography. In other cases, for example, after death, it might be possible to send specimens, suitably preserved, to the rheumatologist responsible for examining the joints for the Foundation. Suitable instructions about this, and any other help required, which may include defrayment of expenses, can then be given according to circumstances.

African Mammals

THE first number of *Zoologica Africana* reports the proceedings of a symposium on African mammals held at Salisbury, Rhodesia, during September 26–28, 1963, under the auspices of the Zoological Society of Southern Africa, when it and a number of visiting delegates were the guests of the University College of Rhodesia and Nyasaland (*Zoologica Africana*, 1, No. 1. Edit. by M. K. Rowan. Pp. 265. Cape Town: Zoological Society of Southern Africa, 1965). The twenty-five papers are gathered into sections on physiology and behaviour, systematics, geographical distribution, population ecology, and wildlife diseases. There are, in addition, opening and closing addresses, a note on latitude-longitude grid maps of Africa, and a record of the resolutions from the Plenary Session of the Congress. The papers covering this very wide field are, as would be expected, of unequal weight, but none is without value; the delegates who attended the symposium returned home with the feeling that it marked the beginning of a new drive in the study of African mammals. The problems to be investigated are almost infinite, and the near-certainty of the drastic reduction and perhaps extinction of the populations of some species emphasizes the urgency of pressing on with the biological study of the African fauna before it is too late. African zoologists are fully aware of the danger to the wildlife of Africa; isolated and handicapped by lack of facilities (as many of them are), they are making the most of their opportunities and, as the results of this symposium show, accumulating a valuable body of knowledge. It is much to be hoped that they will receive the encouragement and backing that they deserve from the various authorities controlling the territories concerned and will be granted the financial aid without which such work cannot be sustained.

Zoological Society of London

THE modernization plans of the Zoological Society of London have made significant progress in 1965. In March, the new Elephant and Rhinoceros Pavilion was opened; in April, the Nuffield Institute of Comparative Medicine was inaugurated and is now fully operative; in May, the first group of birds was installed in the new Snowdon Aviary; in June, the building of the Smal

Mammal House in the Middle Gardens began. In October the Snowdon Aviary was opened to visitors. Among the births in the Collection in 1965 were two red deer and four blackbuck; on the Mappin Terraces wild boars were born and the seven piglets trotting around the enclosure with their mother have been a great attraction. In the Monkey House a tufted capuchin monkey, the first since 1935, and a mandrill were born; and in the Chimpanzee Breeding House, established in May 1964, two female chimpanzees were born but, unfortunately, one has since died. While chimpanzees are perhaps one of the most common of zoo animals, comparatively few are bred in captivity. In recent months, a lion, a puma, a Chinese leopard, two Caracal lynxes, Arctic foxes, a Syrian bear, an American bison and a wallaroo have been born. Among the birds hatched were four Kenya eagle owls, two spotted eagle owls and a barn owl. One of the most exciting additions to the bird collection was a magnificent group of 24 birds of paradise presented by Sir Edward Hallström to mark the visit of Earl Mountbatten of Burma, accompanied by Sir Solly Zuckerman, to Taronga Zoological Park, Sydney. These birds are rarely seen outside Australasia. This superb collection includes the ribbon tail, the sickle bill and lesser superb birds of paradise, the magnificent bird of paradise and the raggi bird of paradise. As part of the same collection, Sir Edward Hallström presented six green pythons, which are some 3-5 ft. long. Lord Chaplin, a former secretary of the Society, brought back from Trinidad an interesting collection of reptiles and amphibians, including four species of frogs new to the London Zoo—the spotted tree frog, the Trinidad golden tree frog, Fitzgerald's marsupial frog and the giant tree frog. The number of visitors to the Gardens in 1965 was considerably higher than in 1964.

Vegetation of Uganda

I. Langdale-Brown, J. A. Osmaston and J. G. Wilson have produced a detailed and authoritative account of the vegetation of Uganda (*The Vegetation of Uganda and Its Bearing on Land-Use*. Pp. 159+24 plates. Entebbe: Government Printer; London: The Uganda High Commission, 1964. 30s.). This will be invaluable for all students of the ecology of the country and for all those engaged in the improvement of land use both for agriculture and livestock production and for forestry. The book is well produced by the Government of Uganda, well illustrated and supported by a substantial folder of maps. It is to be recommended to all those concerned with development in Uganda and to botanists interested in the vegetation of the Equatorial Great Lakes Region.

American Geographical Society: Awards

THE following awards of the American Geographical Society have been presented: *David Livingstone Centenary Medal*, to Dr. Bassett Maguire, for his scientific achievement in the geography of the Southern hemisphere; *Cullum Geographical Medal*, to Prof. K. F. Mather, for distinguished service in the advancement of geographical science; *Charles P. Daly Medal*, to Prof. W. S. Cooper, for distinguished geographical services as a plant ecologist and geomorphologist; *Honorary Fellowships*, to Prof. M. J. Dunbar, for his outstanding contributions to geography through the disciplines of marine science, and to Dr. P. Meigs, in recognition of his work in the problems of water resources, arid lands, climatology and historical geography.

University News:

Belfast

H. R. MARTIN has been appointed to a lectureship in mechanical engineering.

Bristol

THE following lecturers have been appointed: Dr. E. G. Ellison (mechanical engineering); Dr. J. Hindley (bio-

chemistry); Dr. M. S. Knapp (medicine); Dr. F. P. Sayer (theoretical mechanics). The title of professor emeritus has been conferred on the following: Prof. W. Baker (formerly professor of organic chemistry); Prof. R. J. Brocklehurst (formerly professor of physiology).

Leeds

PROF. P. GRAY has been appointed professor of physical chemistry and head of the Department of Physical Chemistry. Dr. F. G. Holliman has been appointed to an additional chair of organic chemistry. Dr. D. R. Baulch has been appointed lecturer in the Department of Physical Chemistry. The title of reader has been conferred on the following: Dr. K. S. Zinnemann (bacteriology); Dr. B. E. C. Nordén (in respect of his post as director of the Mineral Metabolism Research Unit of the Medical Research Council).

London

THE following readers have been appointed: Dr. D. C. Watts (biochemistry), tenable at Guy's Hospital Medical School; Dr. D. W. Allan (mathematics), tenable at King's College. The following title has also been conferred: H. Billett, professor of mechanical engineering, in respect of his post at University College.

Manchester

THE title of professor emeritus has been conferred on the following: Prof. E. W. Anderson (formerly professor of psychiatry and director of the Department); Sir Robert Platt (formerly professor of medicine); Prof. W. Schlapp (formerly Brackenbury professor of physiology and director of the physiological laboratories).

Announcements

Prof. Marcel Nicoler, Dr. Sydney Chapman and Dr. Joseph Kaplan have been awarded the Hodgkins Gold Medal of the American Meteorological Society, for their outstanding contributions to the field of atmospheric research.

THE fourth Matscience Anniversary Symposium will be held at the Institute of Mathematical Sciences, Madras, during January 3-14. Further information can be obtained from the Institute of Mathematical Sciences, Central Polytechnical Buildings, Adyar, Madras 20.

A MEETING of the Biochemical Society will be held in the University of Sheffield during January 5-6. The programme will include a colloquium on "Control of Enzyme Patterns in Tissues". Further information can be obtained from the Administrative Secretary, the Biochemical Society, 20 Park Crescent, London, W.1.

A SYMPOSIUM on "Cutting Costs through the Control of Quality", arranged by the Institution of Engineering Inspection, will be held in the University of Strathclyde on January 6. Further information can be obtained from the Secretary, Institution of Engineering Inspection, 616 Grand Buildings, Trafalgar Square, London, W.C.2.

AN evening meeting of Aslib will be held in London on January 27. The programme will include a lecture by H. A. Chesshyre (Haxfield College of Technology) on "Local Co-operation: a Positive Force". Further information can be obtained from the Meetings Organizer, Aslib, 3 Belgrave Square, London, S.W.1.

THE Royal Institution Christmas Lectures for Young People will be delivered by Sir Bernard Lovell, Prof. F. Graham Smith, Prof. Martin Ryle and Dr. A. Hewish on "The Exploration of the Universe". The lectures will include: introduction and techniques (December 28); the solar system (December 30); the Earth as a planet (January 1); the Milky Way (January 4); radio galaxies (January 6); cosmology (January 8). Further information can be obtained from the Royal Institution, 21 Albemarle Street, London, W.1.

BIOLOGICAL SYSTEMS AT THE MOLECULAR LEVEL

A SYMPOSIUM was organized by the Commission of Molecular Biophysics of the International Union of Pure and Applied Biophysics during September 8-11, under the auspices of the International Laboratory of Genetics and Biophysics, Naples—the local arrangements being made by Prof. A. Buzatti-Traverso.

The first day's discussions, under the chairmanship of Prof. H. A. Scheraga (Cornell), were concerned fundamentally with the problem of predicting the conformations of proteins from their primary structure.

In the first paper Dr. S. Lifson (Rehovoth) gave an account of his recent statistical-mechanical investigations of conformational changes in polypeptides. His method consisted in defining sequences, sequence partition functions and sequence-generating functions and in using them to derive an equation for the contribution of each chain element to the partition function of the whole molecule. The results make possible, for example, an assessment of the relative importance of hydrogen bonding and hydrophobic interactions in determining the conformation of poly-L-alanine at different temperatures.

The remaining papers were more closely concerned with the investigation of specific conformations and the limitations imposed on them by interactions between non-bonded atoms. Given that the conformation of the peptide group is generally *trans* and planar, the most important variables determining the conformation of a polypeptide chain are the angles ψ and ϕ for rotation about the N—C α and C α —C β bonds respectively. Prof. G. N. Ramachandran (Madras) reviewed the earlier work in which he and his colleagues had studied the values of ψ and ϕ that are allowed when fixed minimum distances of approach are set for the atoms of a dipeptide unit comprising the two peptide groups and the β -carbon joined to an α -carbon atom. This had shown that only certain regions in a ψ , ϕ -diagram are sterically allowed and that these regions enclose, or nearly enclose, most of the conformations that have been proposed for polypeptides or observed in analyses of relevant structures. He then described an investigation of the effect of allowing the angle NC α C β to vary by $\pm 5^\circ$ from the tetrahedral value (while the deviations from 110° of the other angles at C α were minimized), which showed that the allowed regions in the ψ , ϕ -diagram are increased, by the introduction of this flexibility, to embrace most of the observed conformations that were previously just forbidden.

Prof. Ramachandran went on to consider the properties of helical polypeptide chains, in which the angles ψ and ϕ are kept constant at each α -carbon, with particular reference to the main chain —NH . . . O hydrogen bonding. He showed that families of helices of the right- and left-handed 3·6 $_{13}$ or α -type and of the 3·0 $_{10}$ type (with hydrogen bonds from peptides 1 to 4, and 1 to 3, respectively) are sterically allowed, with hydrogen bonds of acceptable length that depart from colinearity by less than 30° , provided that the bond angle at C α is close to 110° . On the other hand, right- and left-handed π -helices (1·5 hydrogen bonded) are allowed only when the angle at C α is 115° , and the 2·2 $_{7/2}$ ribbon structure (1·2 bonded) is permitted only with hydrogen-bond-angles greater than 20° . The triple helix structure for collagen with two inter-chain hydrogen bonds (angles of 27° and 30°) for every three residues, as proposed in Madras, falls within a fully allowed region in the ψ , ϕ -diagram, and a new suggestion was put forward that this structure also includes additional CH . . . O hydrogen bonds between neighbouring chains. When collagen has the sequence gly-pro-hyp in all three chains, however, it appears that only one hydrogen bond can occur for every three residues and the preferred structural parameters closely follow those given by Rich and Crick.

Finally, Prof. Ramachandran discussed the conformations of amino-acid side-chains that have been observed in crystal structures, showing (in keeping with earlier reviews) that they usually adopt fully staggered conformations, but that any one of the possible variants may be adopted in response to a particular environment.

Developments of the limiting-contact approach to the analysis of polypeptide conformations were also described by Dr. G. Némethy. In these studies the influence of various amino-acid side-chains on the conformation of the dipeptide unit was investigated, the results being presented again in terms of the allowed regions in the ψ , ϕ -diagram. It was shown that the addition of a γ -carbon atom reduces the percentage of allowed conformations from 16 per cent for C β alone to 14 per cent, even though there are three rotational positions giving staggered conformations of the side-chain from which to choose. The addition of atoms beyond C γ in an unbranched side-chain does not limit the range of allowed conformations any more, but the presence of more than one δ -atom, as in leu, reduces the allowed conformations to 11 per cent of the possible, and branching at C β , as in val, ile or thr, reduces this total to only 4·5 per cent.

From all these analyses by the limiting-contact method it is clear, therefore, that local steric restrictions, quite apart from the interaction of groups widely separated in the primary structure, severely restrict the number of conformations accessible to a polypeptide chain and go some way (though not yet far enough) towards making practicable the calculation of conformation from amino-acid sequence. A general method for handling such calculations has been pioneered by Prof. A. M. Liquori (Naples), and his colleagues, who described his preliminary attempts to calculate the helical conformations of minimum potential energy, taking into account the forces between non-covalently-bonded atoms. These calculations have led to diagrams of the potential energy as functions of ψ and ϕ which indicate, for example, that the right-handed α -helix with the original Pauling and Corey parameters is a very stable conformation even without consideration of the hydrogen-bonding that stabilizes it still further. There are four other potential-energy minima, including one corresponding to the left-handed α -helix which is shown, encouragingly, to be less stable than its right-handed counterpart.

Analysis of the structure of myoglobin has shown that these stable helical values of ψ and ϕ also occur frequently in non-helical regions of the molecule. Prof. Liquori suggested, therefore, that it might be interesting to investigate an idealized structure for myoglobin in which all the dihedral angles were constrained to take the values at the closest of these favoured pairs. Here again, of course, the aim was to reduce the number of conformations that has to be considered to manageable proportions.

Unfortunately there are very few reliable data from which the conformational potential energy of a polypeptide can be calculated. Prof. Liquori presented some evidence to suggest that the general features of the ψ , ϕ potential energy diagram for helices do not depend very sensitively on the exact shape of the interaction potential curves used in the calculations. He emphasized his belief that while precise energy values are not yet available, proper use of the relatively reliable van der Waals's radii may enable progress to be made towards the prediction of conformations.

In a final short paper in this session, Dr. D. C. Phillips (London) described the structure of lysozyme, recently determined at the Royal Institution, remarking particularly on the occurrence in it of some residues forming an anti-parallel pleated sheet and of some others in the conformation of the 3·0 $_{10}$ helix with corresponding hydro-

gen bonding. Nearly all the helices in the molecule appear to be distorted to some extent from the standard α -structure and there is evidence that the hydrogen bonds in them sometimes depart from linearity by 20° or more. He described how comparison of the main features of the structure with the varying hydrophobicity of the amino-acid residues in the primary structure had suggested that the polypeptide chain folds itself from the terminal amino-end, forming first a compact unit with a hydrophobic core, then an extended arm of hydrophilic residues, partly in the β -conformation, and finally a coil that nearly closes the gap between the two parts, leaving a cleft that appears to be the active region, before winding itself around the terminal amino-end. Following ideas developed in collaboration with Dr. P. Dunnill, he noted that analysis of the distribution of hydrophobicity along a polypeptide chain might be useful in predicting conformations if enough guiding principles could be established.

A preliminary calculation of the dihedral angles ψ , ϕ in lysozyme had shown them to be nearly all in allowed regions of a potential energy diagram calculated for a peptide unit by the use of Lennard-Jones type interaction potentials. This diagram, which was similar to that calculated by Brant and Flory, differed from the original limiting-contact diagram mainly in allowing a greater range of conformations near those appropriate to the $3\cdot0_{10}$ and the left-handed α -helices. This was presumably because in these regions the occurrence of marginally short contacts, which are forbidden in the limiting-contact analysis, are outweighed, in the calculation of potential energies, by the presence of a large number of favourable contacts. The effect on the ψ , ϕ -diagram is very similar to that reported by Prof. Ramachandran to result from allowing the $\text{NC}_\alpha\text{C}^\beta$ angle to depart from 110° .

These papers provoked a lively discussion in the course of which Dr. F. H. C. Crick (Cambridge) remarked that the study of allowed helical conformations has really progressed very little beyond the results obtained by Donohue from the careful measurement of models. He urged strongly that rigorous attempts should be made to distinguish the important conformational variables, by comparison of the relative energies involved, from among covalent bond-lengths and bond angles, hydrogen bond lengths and angles, van der Waals's contact distances and rotations about bonds, suggesting that calculations based on simple crystal structures might provide necessary criteria for the establishment of valid energy parameters. Dr. J. C. Kendrew (Cambridge) described the helices found in myoglobin, noting that they are less regular than was first supposed and that some residues, particularly at the carboxyl ends of α -helices, are in the $3\cdot0_{10}$ conformation. There was general agreement that models based only on α -helices and 'random coils' must be considered inadequate. In view of the present very large number of investigations in which peptide conformations are described in terms of ψ , ϕ -diagrams, a plea was made for the general adoption of the standard conventions for labelling rotations that have been drawn up by Dr. G. Némethy. These are shortly to be published in the leading journals.

The second day, under the chairmanship of Dr. G. M. Edelman (New York), was devoted to the structural basis of the immune response. Dr. A. Nisonoff (Urbana) gave an extensive review of work done on structure of immunoglobulins over many years, leading up to the present-day concept of a divalent multi-chain structure consisting of two heavy chains, and two light chains with two antigen-binding sites per molecule. Even specific antibody directed to a single antigen is highly heterogeneous. Four classes of immunoglobulins are known, which share light chains but differ in heavy chains. Although the main antigen-binding site is on the heavy chain, a consensus of opinion is that both light and heavy chains contribute to the configuration of the antigen-binding site. Recent studies suggested that the two heavy chains are held together by only one S—S bond. In closing, Dr. Nisonoff

discussed recent work by Drs. Hilschmann and Craig and Dr. Putnam and his colleagues, who have determined a partial amino-acid sequence of three Bence Jones proteins of type I (equivalent or similar to light chains of type I immunoglobulins). The C-terminal half of the molecule is constant in the three Bence Jones proteins, while the N-terminal half shows wide variation. Dr. Milstein (Cambridge) gave further data on the structures of several antigen proteins and suggested that the results were incompatible with the concept that the variations are due to single point mutations. We all await further sequence studies to throw light on the constant and variable regions of the antibody molecules.

Next, Prof. Jerne (Pittsburg) discussed the cellular kinetics of the antibody response when antigen is injected into the whole animal. Studying haemolytic antibody formation by individual spleen cells, using his plaque assay technique, he observed the events following the injection of sheep red blood cells. There is a rapid rise and fall in the number of antibody-forming cells. Subsequent to the injection of sheep red blood cells one is dealing with a cell population multiplying for a few days, after which time the cells reach an end-stage and do not divide into further antibody-forming cells. Dosage of sheep red blood cells affects the slope of the increase in antibody-forming cells as well as the time (in days) taken to reach a peak number of antibody-forming cells. At low doses of sheep red blood cells only two-thirds of the animals tend to respond and the slope of the increase of antibody-forming cells is much flatter. This is not easily explained by a population of reactive cells multiplying at a certain rate. Prof. Jerne discussed various possibilities. He suggested that perhaps the most likely explanation would be that lymph gland has several compartments, and that contact of antigen with reactive cells can only occur in certain parts of the lymph gland, perhaps the germinal follicles.

In the third paper in this section, Dr. M. Cohn (La Jolla) gave a lucid discussion of the potentiality of single cells. Since it has not been possible to clone antibody-forming cells in tissue culture, three approaches have been used. Different investigators have studied: (1) antibodies formed by single cells; (2) immunoglobulins formed by clones of transplantable murine plasma cell tumours; (3) the use of fluorescent staining techniques to detect different types of immunoglobulins in individual cells. The various studies agreed in finding that at least 90–95 per cent of the cells make only one antibody, one class of immunoglobulin and one type of light or heavy chain. In an investigation testing for genetic markers on heavy chains less than 5 per cent of the cells had a potential to express both alleles. Therefore, only one structural gene appears to be expressed by the majority of cells. The significance of the low percentage of apparently multipotential cells is not clear at present. No two myeloma proteins have been found to be alike. Therefore, the number of possible light and heavy chains must be very large.

In closing, Dr. Cohn discussed theories of antibody formation, germ-line versus soma. Soma would rely on mutation during the life of the cell and be less useful than the germ-line, which would follow Mendelian genetics.

Dr. B. Askonas (London) discussed the processing of antigens and the role of information at macromolecules in the immune response. She stated that the problem of control of antibody synthesis by antigen runs far behind the other problems. The fate of antigen was discussed at the cellular and biochemical level. Radioactive antigen is taken up by phagocytic cells throughout the lymph gland; in the secondary response it is particularly concentrated in the dendritic cells in the germinal centre. Although a major part of the antigen taken up is degraded very rapidly, the remaining antigen persists for weeks and is lost only gradually from the cells. The failure to detect radioactively labelled antigen in antibody-forming cells by G. J. V. Nossal and J. H. Humphrey and their

collaborators has shown that there can be only very few antigenic determinants present in the antibody-forming cell.

The question of how antigen stimulates the potential antibody-forming cell is still a vital problem. Whether it does so by direct interaction with the reactive cell or has to go through an intermediary cell needs further clarification. Since the phagocytic cells, the macrophages, take up the antigen they have been implicated as possible intermediary cells. RNA preparations containing antigen can be extracted from macrophages and they are highly active in inducing antibody, but whether this is an essential step in the induction of antibody is not clear. Suggestions that antigen-free informational molecules are transferred from macrophages to the reactive cells have also been made, but this has not been shown convincingly. Further experimentation is required to throw light on this problem.

On the third day a discussion on allosteric enzymes was held with Dr. F. Jacob (Paris) as chairman. The fact that a combination of one molecule of ligand with a macromolecule can influence the combination of another, the same or different, has been known for a long time. The term 'allosteric' proteins was introduced by Monod and Jacob to describe proteins in which such interactions occur. Although it is to be expected that many proteins are in some degree allosteric, the introduction of this term has been especially useful in directing attention to a particularly important class of phenomena involving enzymes which, potentially at least, provide an explanation of the regulation of metabolic processes in the organism.

The original observations of such interactions were on haemoglobin which may be considered as a type case of an allosteric protein. This was the subject of Dr. Wyman's talk. Dr. Wyman discussed mainly the haem-haem interaction, considered as a model of interaction between sites for the same ligand.

The second speaker, Dr. J. Monod (Paris), described a model which aims at explaining both the interactions between similar and between different ligands, in terms of quaternary structures of proteins. In this model an allosteric protein is considered to be a polymer with an axis of symmetry, which can exist under at least two different states which are assumed to differ between them by the degree of association between the sub-units. The two states are supposed to differ in their affinity for the ligands which the protein can bind so that the presence of a given ligand can push the equilibrium towards a given state.

The third speaker was Dr. H. K. Schachman (Berkeley, California), who gave a physico-chemical description of the enzyme aspartyltranscarbamylase of *E. coli*. Dr. Schachman showed that the enzyme is made of different sub-units, some of which possess a site specific for one of the substrates, aspartate, and others a site specific for CTP which inhibits the reaction catalysed by the enzyme. Isolated sub-units still exhibit affinity for their respective ligand but without co-operative effects, those being restricted to the complex polymer.

In the discussion, many other enzymes were discussed which exhibit similar behaviour. This is the case, for example, of the enzyme dCMP amino hydrolase which has been extensively investigated by Dr. Scarano. In

contrast, other complex enzymes appear to operate on a different scheme. This is the case, for example, of the enzyme glutamine synthetase of *E. coli*, investigated by Dr. E. Stadtman, an enzyme the activity of which is susceptible to partial inhibition by eight different compounds of widely different structures.

In the final session on "Molecular Aspects of Differentiation", with Prof. J. Brachet (Brussels) as chairman, the main topic discussed was the synthesis of nucleic acids and proteins during early development. Prof. Monroy (Palermo) described in detail the significance of the events following the process of fertilization in sea-urchin eggs. Ribosomes from unfertilized eggs are not capable of incorporating amino-acids, while those obtained from fertilized eggs are capable of doing so. Prof. Monroy presented the following simple experiment. When RNA from unfertilized eggs was added to liver ribosomes the latter incorporated amino-acids. But no incorporation was detected when RNA from unfertilized eggs was added to ribosomes from unfertilized eggs. He has therefore suggested that some inhibitor is present on the ribosomes which prevents them from synthesizing protein. Though the unfertilized egg has a store of messenger RNA, the ribosomes become active only after fertilization. Prof. Monroy further indicated that inhibition on the inactive ribosomes could be lifted considerably by treating them with trypsin and removing the trypsin by washing through a sucrose layer.

Dr. D. Brown (Baltimore) examined the synthesis of ribosomal, soluble and DNA-like RNA during development of *Xenopus*. The kind of RNA synthesized varies conspicuously as development proceeds. Dr. Brown has been able to show that DNA-like RNA and soluble RNA are synthesized during late cleavage phase and the synthesis continues after gastrulation. The synthesis of ribosomal RNA starts only at the onset of gastrulation and increases as development proceeds.

The final paper was one on cell interactions and carcinogenesis by Dr. L. Sachs (Rehovoth), who discussed *in vitro* studies on the mechanism of carcinogenesis by polyoma virus and by carcinogenic hydrocarbons. In the experiments with polyoma it was shown that virus infection can induce the synthesis of cellular DNA after normal cell DNA synthesis has been repressed by contact inhibition or by X-irradiation, that each cell is induced to synthesize about double its DNA content, and that this induction is not dependent on the replication of viral DNA, but is a function of the viral genome. It was suggested that all the known experimental findings on cell-virus interactions with the small DNA tumour viruses can be explained by the synthesis of a messenger RNA early after virus infection that mediates the induction of cellular enzymes required for DNA synthesis by way of alteration of the cell surface. In the experiments with carcinogenic hydrocarbons it was shown that these chemicals can directly and rapidly induce *in vitro* a high frequency of transformation of normal cells to tumour cells. Such *in vitro* investigations provide evidence on the similarities between the two types of carcinogenesis.

LIVINGSTONE'S CONTRIBUTIONS TO MEDICINE

DAVID LIVINGSTONE has usually been looked on as a missionary and explorer, yet his contributions to medicine were numerous and varied. A review of them is given by M. Gelfand in a recent issue of *The Central African Journal of Medicine* (11, No. 7, 192; July, 1965).

He qualified as a licentiate of the Royal Faculty of Physicians and Surgeons (Glasgow) in 1840, and throughout

his life, so far as circumstances would permit, he did all he could to keep himself fully informed and up to date. For the greater part of his time in Africa he was tolerant of native practices in medicine, seeking to understand their materials and methods. Patients flocked to him in hundreds, and by the standards of the day he was particularly successful with eye complaints and obstetrics. He was probably the first to describe trypanosomiasis in

cattle, and as early as 1841 he gave arsenic to a mare infected with the disease.

When in the Tete district in 1856 the people were afflicted with a severe epidemic of smallpox, he tried to produce a vaccine by inoculating a heifer, but the inoculation failed to take; instead, he had to send to the Cape for a supply of vaccine. In the same year the Governor of Quelimane requested that he report on the causes of unhealthiness of Senna, a town on the Lower Zambesi. He attributed the ill-health to the low-lying nature of the land, polluted expanses of water, and decomposing vegetable matter.

Among other experiments, he carried out tests on the most suitable colours for clothing in the tropics; he reported on a disease called 'maculo', now no longer occurring in Africa, characterized by a spreading gangrene of the rectum; he described the earth-eating habits of natives in Northern Rhodesia; he wrote a vivid account of tropical ulcer among slaves; and he noticed that Africans living on a manioc diet, high in carbohydrates, suffered from disturbances of vision.

Livingstone was the first to record that the tick (*Ornithodoros moubata*) was the vector for relapsing fever; and he may have also been the first man of medicine to associate mosquitoes with malaria. He was aware of the great British expeditions to the Niger in 1832 and 1841, both of which ended in disaster, and after studying the account by M'William of the second expedition he came to the con-

clusion that quinine was effective against malaria if it was given at an early stage and in sufficient quantity. That led him to devise his pill, consisting of quinine and purgatives, which he was able to try out in a dramatic manner on two English hunters who were dangerously ill with fever at Lake Ngami one companion of theirs having already died. At this time his wife and children also became infected with malaria; he treated them successfully in the same kind of way. It was because of this treatment that he was able to travel right across Africa from west to east in 1856, and maintain activities in the unhealthy areas of the Zambesi and Shire Rivers for more than four years.

Livingstone also deserves credit for some attempts which he failed to carry through. When near the East Coast, for example, he came across trees in the forests of Senna which he thought were cinchonas, and he sent samples to England, only to learn from Kew that he had been mistaken. At another time he tried to prepare chloroform for his wife when her baby was due; he had obtained some chloral hydrate, having read of Simpson's discovery, but lacked a suitable retort to prepare the anaesthetic. On a further occasion he made use of electricity in treating a Mr. Hamilton in Bechuanaland who was suffering from paralysis.

In all these endeavours and discoveries Livingstone was moved by a pure missionary spirit, never seeking to make use of his medical knowledge for pecuniary gain.

CHEMISTRY OF PLANT PIGMENTS

A SYMPOSIUM on the chemistry of plant pigments, organized by the Phytochemical Group, was held in the University of Aberdeen on September 23-24. Attention in recent years has been given increasingly to pigments which are not readily analysed by conventional techniques either because of their lability or their intractability, and most of the substances discussed during the first day of the meeting fell into one or other of these two classes. Progress in the chemistry of the betacyanins and betaxanthins, for example, has been delayed because of their susceptibility to aerial oxidation during purification. In the first paper, Prof. M. Piattelli (Naples) described how he was able to separate these elusive nitrogenous colouring matters by fractionating plant extracts on polyamide columns. He found them occurring in plants of the Centrospermae as glycosides. Betanidin was the only aglycone of the many betacyanins, but he had discovered as many as eight betaxanthin aglycones. These yellow pigments were found to be related in structure to betanidin and differ in that the leucodopachrome moiety of betanidin is replaced by proline, 4-hydroxyproline, glutamine, glutamic acid, aspartic acid, tyramine, dopamine, or methionine sulfoxide.

In the second lecture, Dr. F. G. Holliman (Leeds) summed up the results of several years work on the red phenazine pigments present in *Pseudomonas aeruginosa*. He presented convincing structural and synthetic evidence that they are 2-amino-10-methylphenazinium betaines. One of them, aeruginosin B, is unique as a natural product in having a sulphonic acid group on a heterocyclic system, and furthermore is only the second natural sulphonic acid to be discovered, the first being the sulpholipid sugar moiety, sulphoquinovose. In the third paper, Prof. W. B. Whalley (London) also dealt with a *Pseudomonas* pigment, this time a blue pigment in *P. lemmonieri*. The compound, which analysed for CHON and the metal calcium, proved to be extremely intractable and did not respond to any of the usual physical methods of structure determination. After many attempts, Prof. Whalley eventually isolated a degradation product from chromium trioxide oxidation, a

pyridone quinone with an *n*-octyl side-chain, but the full structure of the pigment remains to be elucidated.

The afternoon session was devoted to the natural black pigments and began with an account of the melanins by Prof. R. A. Nicolaus (Naples). After discussing the chemical structure of sepiamelanin from cuttlefish ink, he went on to point out that whereas all animal melanins examined (19 sources) were derived from 5,6-dihydroxyindole, plant melanins, such as that in *Ustilago maydis* spores and in nine other sources, were derived from catechol. The question was raised, in discussion of this paper, whether plant melanins could justly be called melanins, since they did not contain nitrogen, and should instead be called humic acids. However, humic acids, as were described by Prof. R. D. Haworth (Sheffield) in the following paper, are organic pigments present in the soil, formed from decaying vegetation over the course of centuries. After a brief survey of the chemistry of humic acids, Prof. Haworth went on to outline his own recent investigations, which were based on the discovery that these compounds give electron spin resonance signals. He thought that humic acid consisted of an organic polycyclic 'core', which was responsible for electron spin resonance signals, to which metals, carbohydrates, phenolic and amino-acids are attached. He supported this view with the results from zinc dust distillation of humic acids, which had produced xanthone, anthraquinone and a series of alkylnaphthalenes. Dr. H. M. Hurst (Liverpool), in a paper on the phenolic moieties in humic acid, described how he had obtained more than 30 phenolic compounds, all being lignin and flavonoid derived units, from mild reduction of humic acids with sodium amalgam in weak alkali. He suggested that humic acid was a polymer derived mainly from lignins and flavonoids, which, after microbial degradation, were leached by rain-water from decaying leaves and deposited in the podzol. In the final paper on humic acids, Dr. R. I. Morrison (Macaulay Institute, Aberdeen) reported that, by oxidizing methylated humic acids with permanganate and identifying the products by gas chromatography, he had also obtained lignin-derived fragments. The products

he identified included anisic, veratric, 3,4,5-trimethoxybenzoic, 4-methoxysophthalic and isohemipinic acids.

The first paper presented on the second day was by Dr. J. C. Hughes (Norwich) and carried on the theme of humic acids, since it dealt with black and brown pigments formed in the potato after cooking or as a result of enzyme action. Production of the black pigment, an iron-chlorogenic acid complex, in cooked potatoes was greatly affected both by biochemical factors in the potato and by the environmental conditions in which the potato was grown; it could largely be prevented by adding citric acid to the cooking water. The level of browning, on the other hand, is determined principally by the amount of substrate (tyrosine) and not the amount of enzyme (phenolase) in the potato. Turning from vegetable to flower pigments, Prof. E. Bayer (Tübingen) then described his work on naturally occurring anthocyanin metal complexes. Protoecyanin, the natural chelate in cornflowers, he showed, can be split to cyanin, polygalacturonic acid, iron and aluminium. He pointed out that the reason why cyanin, present in red roses, would not complex with metal to give a blue colour was because chelating metals in these petals are not freely available, as they are bound to other substances of higher complex stability.

Anthocyanin pigments occur widely in leaves as well as flowers of higher plants and are abundantly present, for example, in leaves of the Asiatic *Coleus* species from which the popular ornamental plants are derived. However, Prof. H. Eugster (Zurich), in examining the red pigments on leaves of East African *Coleus* spp., found, not anthocyanins, but some new types of quinonoid pigments. The structures of two, coleon A and B from *Coleus ignarius* (fam. Labiatae), proved relatively easy to determine; A is a 2,5-hydroxynaphthaquinone with an isoprenoid attachment and B is a related hydroquinone. Fuestion, from *Fuerstia africana* (also Labiatae), proved to be unusually labile, being sensitive to acid bases and heat, but, by very skilful experimentation, Prof. Eugster had been able to show that it was a methylene-quinone, somewhat related in structure to pristimerine.

Yellow xanthone pigments were the subject of the next paper by Dr. J. C. Roberts (Nottingham), who surveyed their occurrence in flowering plants (nine families), in fungi (three genera) and in lichens (one genus). He described methods of structural determination, and dealt specifically with the identification of sterigmatocystin from *Aspergillus versicolor* and mangiferin from *Mangifera indica*. The latter xanthone has a *O*-glucosyl attachment and it thus formed a natural bridge to the next paper on naturally occurring *O*-glycosyl compounds by Prof. L. J. Haynes (Jamaica). He described the nuclear magnetic resonance evidence which supported *O*-glycosyl structures for mangiferin and related compounds, and outlined recent research on a new *O*-glucosylchromone in bitter aloes. The final paper by Dr. R. M. Horowitz (Pasadena) was on *O*-glycosylflavones, and in it he presented nuclear magnetic resonance evidence which proved that vitexin was 8-*O*-glucosylapigenin, isovitexin 6-*O*-glucosylapigenin and the lucenins 6,8-di-*O*-glucosyl-luteolins. He used similar data in very elegant fashion to show that the xylose in a *D*-xylosylvitexin (isolated from oranges) was attached by a $\beta 1 \rightarrow 2$ link to the 8-glucosyl residue, and that a *p*-hydroxybenzoic acid derivative of vitexin was similarly constituted.

The meeting ended with short reports on the xanthenes in *Kielmeyera* spp. (M. T. Magalhaes, Brazil) and in *Calophyllum* spp. (F. Scheinmann, Salford), on the quinones in *Tabebuia ipé* (A. R. Burnett, Aberdeen), on a novel yellow fungus pigment from *Paxillus involutus* (R. L. Edwards, Bradford), on umbelliferone biosynthesis (D. J. Austin, Glasgow), and on the *Aspergillus* hydroxylating system (S. M. Bocks, Oxford). It was clear from this symposium that plant pigments continue to provide a challenge to the skill and ingenuity of the organic chemist and that problems remain which will take much effort to solve, unless dramatically new techniques become available. The attraction of their colour will always ensure abundant interest in the chemistry of these fascinating substances.

J. B. HARBORNE

DESIGN METHOD

THE OXFORD DICTIONARY lists many different interpretations of the word 'design' used either as noun or verb, but it now has a new meaning in its own right: a subject to be studied for its own sake, regardless of any primary discipline involved. Design as a fundamental concept is on its way to becoming a science. In the sense of producing new and useful commodities of all kinds, it is seen as a major challenge to human ability. "The better understanding of the problems involved provides a task for the behavioural scientists. The better development of designers requires careful thought by management." The theoretical and practical values of pioneering inter-disciplinary thinking in the broad field of design had to be tested. That the task has proved more than successful is attested by the symposium sponsored by the Design and Innovation Group of the University of Aston in Birmingham (designate), convened in Birmingham during September 21-23, of which a copy of the preprints of the papers presented is now available*.

This volume undoubtedly brings together, in a substantial way and for the first time in Great Britain, the general trend of thought about the nature and problems of design by many different people in many walks of life having wide experience in this field. Thirty papers dealing with design from inception to realization and utilization are included. Breadth of coverage is shown by the wide range of technologies and sciences represented; these are

architecture, behavioural sciences, chemical engineering, electrical engineering, electronics, ergonomics, fuel technology, information science, instrument technology, mechanical engineering, metallurgy, philosophy, physics, production engineering, psychology and sociology.

As if to emphasize the concept of the building and ultimate evolution of design science, the symposium is appropriately divided into six successive sections: (1) the design process; (2) human needs and satisfaction; (3) stages of design; (4) practical design and techniques; (5) realization; (6) design and management.

The design process is concerned with overviews of the total process of design. It is illustrated by five papers: "Design Methods Reviewed", by J. C. Jones; "Some American Views on the Design Process", by R. J. McCrory; "A Survey of Design Methodology", by W. E. Eder; "Preparatory Work for Research into Electronics Design", by H. V. Beck; and "Design Science", by S. A. Gregory. On the bases of experience in these fields, it is deduced that the time is ripe for research into design and the establishment of design science as an aid to the practical designer.

"All technological design attempts to fulfil some human need or provide some satisfaction." The section on human needs and satisfaction is concerned with establishing the concepts involved and exploring ways of finding out or measuring human needs. Herein, to guide constructive thinking, are a further five papers: "Design and Human Satisfaction", by W. H. Mayall; "Invention, Design and Market Research", by A. F. Stobart; "Sociology and

* *Design Method Symposium*, University of Aston in Birmingham Designate (College of Advanced Technology), September 21-23, 1965—Preprints (Organized by the Design and Innovation Group.) Pp. 322. (Butterworths, London, 1965.)

Design", by A. M. Penny; "Ergonomics and Design", by B. Shackel; and "Choosing and Evaluating", by A. G. Pleydell-Pearce.

The foreword to the section on stages of design reads: "From the perception of need it is possible to set down the design process in successive stages. These stages are not intrinsically isolated but may be conveniently separated for the purpose of description and study. In practice the operations involved in the sequence continually re-define each other until a solution satisfactory for the particular circumstances arrives." In support of this dictum are again five papers: "The Elements of Design", by R. D. Watts; "Information for Design", by J. E. L. Farradane; "Patterns", by A. D. Newman; "Creativity", by G. H. Broadbent; and "Design and Decision", by S. A. Gregory.

The theme of practical design and techniques is an analysis of the methods that designers are finding useful and consideration of progress in application of new ideas. In this section we get down to what may be termed the day-to-day function of the designer in certain fields, rather than the more philosophical aspects of his work. "Designers, in reporting their work, tend to concentrate upon the more technical aspects of the task." But there is more to it than this, as is apparent from these papers: "A Practical Design—An Oil Burner for Large Water-tube Boilers", by A. M. Needham; "The Implications of Economics in Engineering Design", by A. P. Shahbenderian; "Models", by C. Hulse; "The Use of a Digital Computer in Design Offices", by K. C. Parton; and "Fundamental Design Method", by E. Matchett and A. H. Briggs, an interesting case of how a combination of systematic method and psychological stimulation contributed to the production of a useful design.

In the section on realization, the underlying motive is that eventually all practical designs, if successful, must come to a material embodiment. This demands study of the interaction of function, fabrication techniques, number and complexity of products. In this concept such interaction affects assembly, reliability, maintenance, best use of space, and overall cost. All decisions made in this category must be communicated to everybody involved, to make this goal of realization truly effective. To show how this can be done, F. L. Ellis contributes a paper on

"Design Realization"; "Selection of Materials" is discussed by A. L. Davies; a paper by C. T. Corney entitled "Reliability and Maintenance" is followed by one on "Design of Materials", by S. A. Gregory, while a welcome note on "New Ideas in the Drawing Office" is struck by P. McMullen.

The final section on design and management probably goes to the root of the whole project of a design science, in that it seeks to equate formulation of policy, operation and motivation of working groups, effect of major organization on design, and methods of evaluating the effectiveness of design organizations as a whole, as a matter of fundamental concern. The exponents in this argument are B. T. Turner, in his paper on "Design Policy Formulation"; R. Davis in his "Innovative Design is a Policy Function of Directorship", wherein it is emphasized that relationship between design and the whole enterprise of which it forms part must be carefully established and the overriding policy laid down for all concerned to appreciate and act on; I. M. Ross discusses "Effect of Organizational Procedures on Design"; M. E. Peplow, "Design Acceptance"; and finally C. H. Buck, who has written an admirable summary of the proceedings at the symposium, enclosed with this volume, contributes his share on the vital subject of "Communication".

There is no doubt that this symposium, and what will follow from it, breaks new and profitable ground. Pressure towards a rational analysis of activities involved in the process of design has, of recent years, steadily increased. Previously in Great Britain, stimuli in this direction were the outcome of the Feilden Report (*Nature*, 206, 643, 1965), the 1962 Conference on Design Methods, and the Scarborough Conference on Teaching of Engineering Design in 1964. This volume shows that we have gone a long way from the impetus of those deliberations and in a comparatively short time. It is the intention of Butterworth and Co. (Publishers), Ltd., to issue a version of the *Proceedings*, together with discussion, suitably edited by S. A. Gregory, on behalf of the Design and Innovation Group, which will make available in durable form the wealth of new information and ideas implicit in and realized by this important symposium: thus is a new science born.

VALIDITY OF RADIOCARBON DATES ON BONE

By DR. M. A. TAMERS and F. J. PEARSON, jun.

Department of Chemistry, Instituto Venezolano de Investigaciones Científicas, Caracas, Venezuela, and Radiocarbon Dating Laboratory, University of Texas, Austin

A SURVEY of the scientific literature reveals the fact that carbon-14 dates on bone often do not accord with independent estimates of the site ages. Bone dates are generally regarded as considerably less reliable than determinations using charcoal, wood, or other materials with large carbon contents (except shell). Most laboratories are in agreement that, whenever possible, bone should not be used for radiocarbon dating.

However, in many instances important finds are made where the only datable material available is bone. A problem illustrating this is the well-known palaeo-indian site, Muaco, in Venezuela¹, which is a kill site. No charcoal was found associated with the animal bones and human artefacts. Two specimens of the bones have given carbon-14 ages of $16,375 \pm 444$ B.P. and $14,300 \pm 500$ B.P.², which are the oldest dates associated with human habitation in South America. Furthermore, these dates fall within a period (between 12,000 and at least 25,000 years ago) in which there was little or no human activity in North America, as evidenced by the scarcity of radiocarbon dates of these ages. A serious controversy has

arisen as to whether the Muaco site is really as ancient as the radiocarbon dates indicate or whether it is possible that radiocarbon dating of bone can give falsely old ages.

The validity of radiocarbon dates on bone is investigated by determining the natural carbon-14 concentrations of samples of known age, that is, historically dated specimens or those found associated with charcoal or other materials known to give reliable radiocarbon dates. Several radiocarbon dating laboratories have measured known-age bone samples with varying results. Recently, Berger, Horney and Libby³ have concluded that, with an acid-dissolving preliminary treatment, bones will be capable of reliable radiocarbon ages. Dates on bone not so treated can give incorrect ages, but there is no indication of evidence that the errors could be such as to make the bone samples appear older than they really are (which is the question in the Muaco site) and insufficient data to permit conclusions as to the extent of the errors involved. Furthermore, it seems reasonable to investigate in more detail the reliability of the special preliminary treatment, used to

remove carbonates completely, with more samples in order to improve the knowledge of the limits of confidence of these bone dates. This article presents the results of a series of measurements on known-age samples and allows the errors connected with bone dating to be defined.

Carbon in bone is present as organic material and as carbonate. It might be expected that the carbonate portion would undergo isotope exchange with carbon dioxide from the atmosphere or soil atmosphere, or with carbonate dissolved in ground water. Thus, a radiocarbon date based on total bone carbon could be falsely young if the bone carbonate had exchanged with atmospheric carbon dioxide or falsely old if the exchange had been with dead limestone-derived carbonate in ground water. However, independent considerations indicate that the carbonate portion of bones can give carbon-14 dates that are incorrectly young, but not too old. This is seen by examining what is known about carbonate exchange processes in general. Laboratory experiments⁴ have shown that carbon dioxide gas exchanges readily with wet, solid carbonates, but that exchange between solid carbonate and dissolved HCO_3^- or CO_3^{2-} was not observed. Recent work on natural systems^{5,6} shows that no isotope exchange between carbonate species dissolved in ground water and the solid carbonate of the aquifer can be detected. Therefore, it is to be expected that the carbonate of bones could be made falsely young by isotope exchange with atmospheric carbon dioxide, but they should not appear falsely old owing to exchange with limestone-derived dissolved carbonate, since this type of exchange does not seem to take place.

In the work described here, the bone as submitted was scrubbed and washed thoroughly and, if necessary, broken into pieces of a few centimetres length. After this, the following treatment methods were investigated:

A-Fraction. The cleaned bone pieces were placed in a large beaker, dilute hydrochloric acid added and the solution heated to boiling. Enough acid was used to dissolve the bones, thus assuring the complete removal of carbonates. Prolonged heating evaporated the solution to dryness. The residue was burned in a stream of oxygen in the usual manner and the carbon dioxide collected for analysis.

B-Fraction. A weighed amount of bone was treated in an enclosed system with an excess of hydrochloric acid. The procedure was carried out in an apparatus similar to that used for shell and other carbonate samples, so that the evolved carbon dioxide could be collected quantitatively. This fraction represents the carbon present in the bone as acid soluble carbonates.

C-Fraction. For some samples, clean bone pieces were burned in oxygen directly, after only a superficial washing with dilute hydrochloric acid (about 5 min at room temperature). It has been demonstrated several times in the course of these experiments that this treatment is not sufficient to completely remove the carbonates present.

Fractions *A* and *B* will provide the most useful data since they represent separate portions of the bone carbon. Fraction *C* gives ambiguous results; it is carbon that comes from a more or less quantitative collection of that present as what could be extracted as fraction *A*, but only part of the carbonates of fraction *B*, since the combustion temperatures are not high enough to completely decompose the calcium carbonate in the bone. This is seen by the fact that the amount of carbon extracted as fraction *C* on a particular bone sample is almost always a little higher than fraction *A*. Furthermore, the carbon-14 dates on the fraction *C* usually differ from those obtained on fraction *A* and in a direction that can be explained by considering the carbon-14 age observed for fraction *B*. A good illustration of this is our sample *Tx-164*, which was a collection of pieces of the shell of a large turtle, now extinct⁷.

Tx-164-A. Fraction *A* was examined in two separate lots which gave 0.45 and 0.64 per cent as the organic

carbon contents of the bones. The combined sample dated $15,800 \pm 1,600$ B.P.

Tx-164-B. There was 1.2 per cent carbon as fraction *B* in the single lot of bones investigated. The carbon-14 date was $8,780 \pm 250$ B.P.

Tx-164-C. This fraction *C*, from bones washed for 5 min in dilute hydrochloric acid, showed a bone carbon content of 0.95 per cent and dated $10,250 \pm 250$ B.P.

If it is assumed that the fraction *A* carbon content of the bones used for the *Tx-164-C* analysis was the average of that found for *Tx-164-A*, that is, 0.55 per cent, and that the organic fraction of *Tx-164-C* was completely collected, but the carbonate fraction only partially (the 0.95 per cent carbon content was made up of a 55 per cent fraction *A* carbon content and 40 per cent fraction *B* content), the weighted averages of the ages of *A* and *B* would indicate that *Tx-164-C* should date 12,800 B.P. The difference between this and the observed age can be accounted for by the quoted statistical errors of the countings.

The same sort of analyses were made with the different fractions of samples *Tx-162*, *Tx-163*, *Tx-229*, and *Tx-231* shown in Tables 1-3. Assuming an uncertainty of 15 per cent in the carbon concentrations, the observed ages of the fractions *C* could be accounted for by considering those given by the fractions *A* and *B*, as was already described here for the turtle bones sample *Tx-164*.

The results of analyses of known-age bone samples are shown in Tables 1-3. The specimen numbers with *Tx*-indicate measurements done at the University of Texas, and those with *IVIC*- at the Instituto Venezolano de Investigaciones Cientificas. Both radiocarbon dating laboratories convert the samples into benzene^{8,9} and count with liquid scintillation techniques. The errors quoted with the dates are the standard errors calculated from the random nature of the disintegration process. A previous investigation has verified that all other laboratory errors, such as isotope effect, amount to less than 0.5 per cent and are negligible for our purposes¹⁰. The dates in the tables, except where indicated, are in years B.P., that is, years before 1950, and are calculated using a carbon-14 half-life of 5,568 years. A description of the sites, conditions of the finds, and references to the associated charcoal ages can be found in the bone sample references quoted in Tables 1-3.

The deviations of the observed carbon-14 bones ages from the presumably correct associated charcoal ages are given in the last columns of Tables 1-3. A negative deviation indicates that the bone age is falsely young. In all measurements the bones dated either the same age (statistically indistinguishable) as the associated charcoal or were younger. The most common method of bone sample treatment, fraction *C*, is the least successful and has given an incorrect date in every case measured. There are also samples quoted in the literature using treatments similar to fraction *C* (refs. 11-16), all of which show bones with falsely recent dates. This is of interest in the case of the Muaco site, mentioned in the introduction of this paper, whose bones were dated with this type of treatment. The indications are strong that the Muaco specimens are at least as old as the controversial carbon-14 dates claim and not younger as has been suggested.

Bone dates on the acid-soluble carbonate portion (fraction *B*) hold no promise of accuracy. Samples of this sort appearing in the literature also show bone carbonate ages incorrectly young¹⁵⁻¹⁷. Radiocarbon dating laboratories are in general agreement that carbonates are particularly suspect materials for dating owing to their ease of exchange with contemporary carbon dioxide.

The most interesting of the methods investigated is the acid-dissolving pretreatment which produces fraction *A*. Table 1 shows that one-third of the samples gave correct dates, but that the others all have negative deviations indicating bone ages that are too young. The reason for this is probably contamination with more recent or

contemporary organic material in the ground. Bones, being very porous, are difficult to clean thoroughly and this is the major origin of the difficulties. The known-age bone samples of Berger, Horney, and Libby³ show the same phenomenon. Their Chimney Cave mummy was presumably not exposed to ground contamination and gives a correct age. The other two samples both date too recent, but the bones from Santa Rosa Island are not in error enough to be statistically distinguishable from the associated charcoal. There are other examples of bones dated with treatments similar to fraction A; several specimens give correct ages¹⁵⁻¹⁸ but others have dates clearly too recent^{15, 16, 19, 20}.

Contrary to widespread opinion, bone samples which were charred do not give more reliable dates than those that were not. However, there seems to be a tendency for bones with low organic carbon concentrations to produce worse results than the others. Charred bones generally have higher organic carbon contents than those that were not burned.

In conclusion, it can be seen that the majority of radiocarbon dates on bone are in error. Most of the bone dates appearing in the literature were obtained with acid-washing pretreatment methods similar to that described as our fraction C. Very few of these values should be correct, except possibly in those situations where the bones were not buried or for relatively recent sites (less than a few hundred years old). The use of the carbon present as acid-soluble carbonates for the dating is not advisable in any case. The best method is clearly that involving the acid dissolving of the bones, in this way ensuring the complete removal of the carbonate fraction. However, even this treatment gives incorrect dates in more than half the samples and the results should be used with caution.

A very important factor in the errors connected with bone dates is that in all cases of measurements on known-age bones, both those presented in this paper and samples described in the literature, the observed errors are in the same direction, that is, giving falsely young ages. It can

be suggested, on the basis of this evidence, that a more realistic use of bone dates would be to take them as only lower limits and to precede the dates with a sign indicating 'greater than or equal to'.

The extent of the errors is not such as to make bone entirely unsuitable in cases where an upper limit to the age of the material is of principal interest. As expected, the absolute values of the deviations tend to increase with the sample ages. For the bones described in this paper, which range from 200 to 10,000 years old, the maximum error is 3,000 years. In the best of the treatment methods (fraction A), only one sample out of the fourteen measured has an error greater than 2,000 years. With scrupulous physical cleaning of the bone specimens, it might be hoped that the errors of unknown-age samples, up to at least 10,000 years old, will not exceed a few thousand years.

REGIONAL GEOCHEMICAL RECONNAISSANCE APPLIED TO SOME AGRICULTURAL PROBLEMS IN CO. LIMERICK, EIRE

By PROF. JOHN S. WEBB and W. J. ATKINSON

Applied Geochemistry Research Group, Department of Geology, Imperial College of Science and Technology, London

TOXIC levels of selenium and molybdenum in soils and herbage have been reported by the Irish Agricultural Institute at a number of localities, notably in Counties Limerick, Tipperary and Meath¹⁻⁵. The clinical symptoms exhibited by cattle and horses in the affected areas, and the composition of the local rocks, soils and plants, are described in detail in the references cited. In consultation with the Agricultural Institute, these areas were included in a preliminary investigation of the application to agricultural problems of regional geochemical reconnaissance techniques, originally developed for purposes of mineral exploration. The results of these trial reconnaissance surveys, based on stream sediment sampling at a density of 1 sample per sq. mile, disclosed anomalous patterns for molybdenum in each of the suspect areas where this metal had been recorded in the soils; patterns of anomalously low values for cobalt were also observed in a cobalt-deficient area in Co. Wicklow⁶. Since then, our investigations have been extended to include selenium, with special reference to the toxic area in Co. Limerick. Here, more detailed sampling has shown an encouraging degree of correlation between the regional distribution patterns of selenium and molybdenum in the drainage on the one hand and in the soils and herbage on the other. The following description is concerned solely with the empirical results of the systematic surveys that have been carried out in the Limerick area and which are now providing the basis for further investigations of more fundamental aspects of this biogeochemical problem.

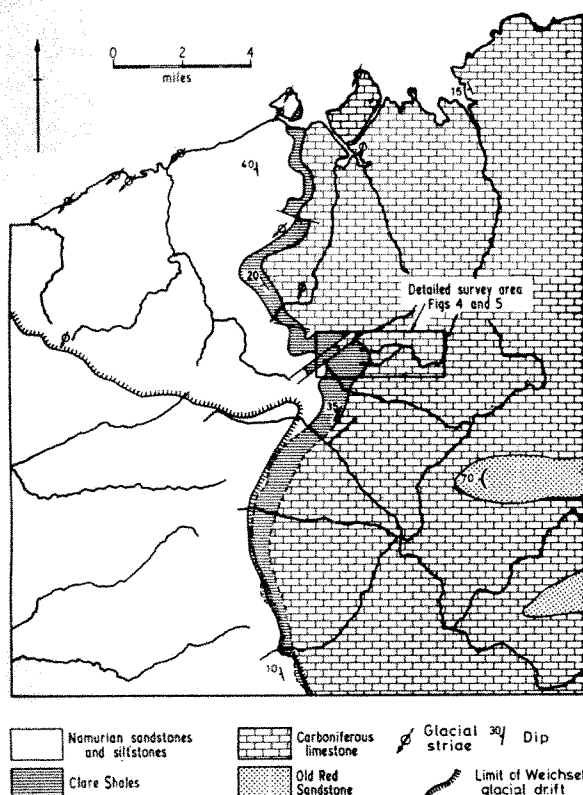

Fig. 1. Simplified geology of the area covered by the regional geochemical survey, Co. Limerick. (After Hodson and Le Warne⁷ and Irish Geological Survey)

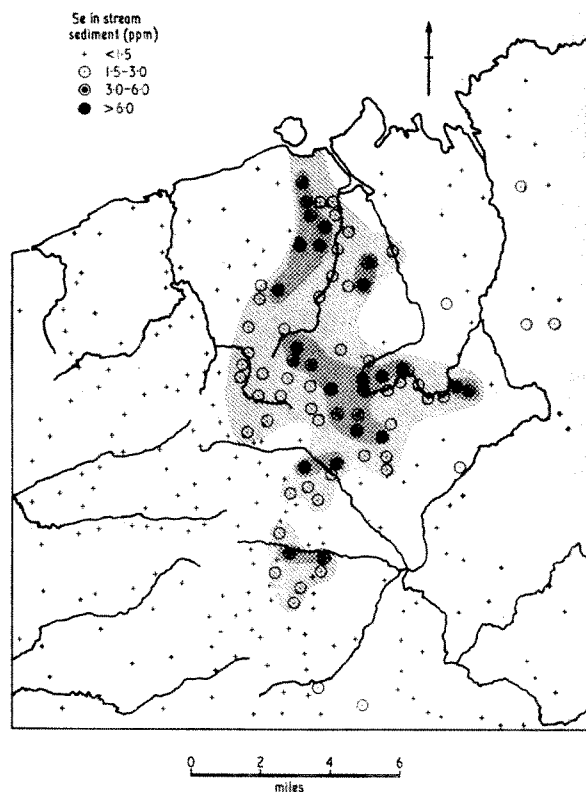

Fig. 2. Distribution of selenium in the stream sediment of tributary drainage (data refer to -80-mesh fraction)

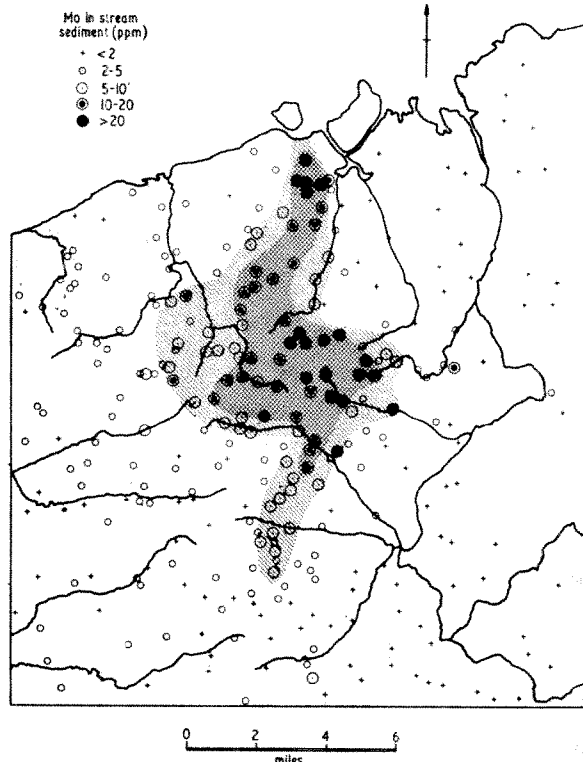

Fig. 3. Distribution of molybdenum in stream sediment of tributary drainage (data refer to -80-mesh fraction)

Description of the study area in Co. Limerick. The geology of the area (Fig. 1) is composed of Carboniferous limestone overlain in the west by a Namurian sequence of sandstones and siltstones at the base of which occurs a black marine shale horizon, defined as the Clare Shales⁷. Cross-sections of these shales, previously noted as the source of the selenium and molybdenum in the affected soils^{3,4}, have been sampled systematically in detail and show bands ranging in content from 5 to 30 p.p.m. selenium and 5 to 150 p.p.m. molybdenum; the higher values usually being recorded in the more carbonaceous and pyritic horizons. By comparison, the limestones, sandstones and siltstones generally contain less than 1 p.p.m. selenium and 2 p.p.m. molybdenum.

Geomorphologically, the boundary of the arenaceous rocks and the Clare Shales marks a more or less well-defined scarp overlooking the lower ground underlain by the limestone. Boulder-clay with local patches of fluvio-glacial gravels cover much of the area, except in the south-west where the overburden is predominantly residual in origin (Fig. 1). Peat is commonly developed on the higher ground and in boggy depressions at the base of the scarp.

Drainage is to the east and west of the watershed, which follows approximately the outcrop of the sandstones immediately overlying the shales. Streams mostly rise in peaty areas. In the upper reaches, the banks are usually composed of colluvium where the streams are incised, but on the flatter ground variable widths of flanking alluvium are developed. As is common in many parts of Eire, appreciable stretches of the stream channels have been modified by dredging.

The agriculture of the area is based on dairying, with small units ranging from about 20 to 40 acres at the base of the scarp to larger farms of up to 200 acres on the limestone in the east. Unfenced hill land to the west is associated with poorly drained peaty soils of low nutritional status and supports low-yielding cross-bred cattle.

The geochemical patterns. For reconnaissance purposes, samples of the active stream sediment were taken from tributary drainage at a mean density of 1 sample per sq. mile. A total area of 250 sq. miles was covered, centred on the known seleniferous localities. The unground minus 80-mesh fraction was analysed spectrographically for 15 elements including molybdenum⁹, and colorimetrically for selenium using a rapid method based on 3,3'-diaminobenzidine capable of 25 determinations per man-day¹⁰.

The resulting patterns show broadly coincident anomalies for molybdenum and selenium covering an area of about 30 sq. miles. Peak values up to 200 p.p.m. molybdenum and 110 p.p.m. selenium occur on or near the Clare Shale sub-outcrop (Figs. 2 and 3). The extension of the anomaly on to the Namurian rocks to the west is related to the glacial dispersion of Clare Shale material in a south-westerly direction up to the limit of the drift deposited during the last (Weichsel) glaciation, as mapped by the Irish Geological Survey (Fig. 1). The apparent extension eastwards on to the limestones is largely due to alluvial transport along the present-day surface drainage system. Copper and vanadium also show a tendency to follow molybdenum and selen-

ium, though contrast between anomaly and background is much less marked. Dredging operations in the stream channels appear to have had little influence on the regional patterns of metal distribution in the stream sediments.

In order to determine the significance of the stream sediment patterns in terms of the metal content of the local soils and vegetation, more detailed sampling was undertaken in the area centred on two known toxic selenium localities (Figs. 1 and 4). In addition to close-spaced stream sediment samples, the soil and pasture herbage were collected systematically on an 880-ft. square-grid giving a total of 220 sampling points over 5 sq. miles. The patterns obtained by analysis of the stream sediment, the minus 80-mesh fraction of the soil at 18-24 in. and the oven-dried mixed herbage are shown in Figs. 4 and 5.

Focal points of the stream sediment anomalies are clearly related to extensive areas of molybdenum- and selenium-rich soils. The drainage trains extend downstream for 1-2 miles and are believed to have developed largely by erosion of metal-rich soil in the headwaters. The stream waters draining the Clare Shales are also anomalous and carry up to 60 p.p.b. (parts per billion,

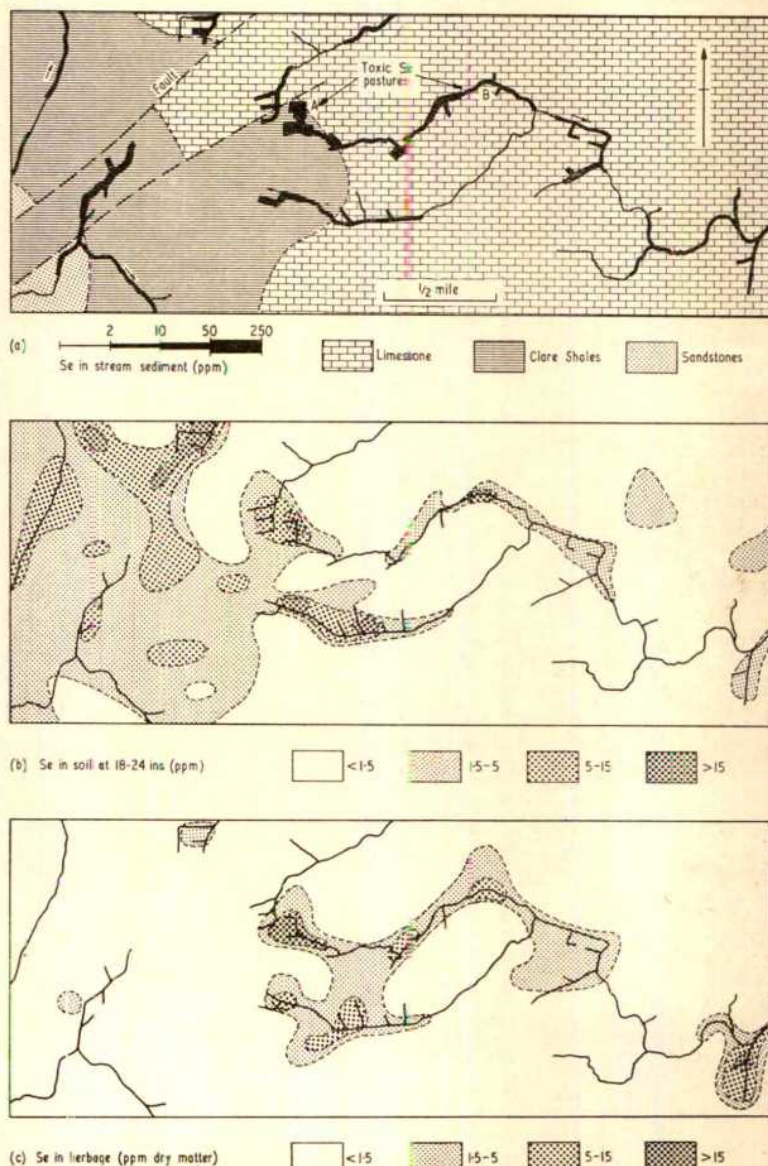

Fig. 4. Distribution of selenium in stream sediments, soil and mixed herbage (data based on 220 samples collected on an 880-ft. square-grid); geology (after Hodson and Le Warne⁷) also shown in 4(a)

10⁻⁹) molybdenum and 17 p.p.b. selenium compared with background values of less than 0.5 p.p.b. The possibility that precipitation of metal from the stream waters may contribute to the sediment anomaly cannot, therefore, be discounted at this stage.

The greater part of the extensive anomalous soil patterns in the west is related to the metal-rich glacial overburden and patches of residuum derived from the Clare Shales. Peak soil values ranging up to 3,000 p.p.m. molybdenum and 500 p.p.m. selenium occur mainly in boggy seepage areas in the stream headwaters where the metals have accumulated by precipitation in the organic-rich reducing environment (as reported by the Irish Agricultural Institute). This view has been confirmed by analyses of ground-water draining into these areas from the Clare Shales, which have been found to contain up to 7.0 p.p.b. selenium and 15 p.p.b. molybdenum compared with background values of less than 0.5 p.p.b. Recent analysis has also shown an additional trend, particularly evident in the case of molybdenum, for the metals to follow iron in seepage soils and spring sediments. The extensions of the soil anomalies down the

valleys are confined to the metal-rich alluvium deposited alongside anomalous streams and which overlies essentially barren limestone drift.

Analysis of grab samples representative of the mixed herbage at each soil sample point shows an interesting contrast in the soil-plant relationships for molybdenum and selenium. Broadly speaking, there is some degree of correlation between the total molybdenum content of the soil and herbage irrespective of local variations in soil-type. In contrast, selenium-rich herbage is found only on the more alkaline, organic-rich poorly drained soils within the seleniferous area. Without denying their influence, local variations in soil type would, therefore, seem to be less restrictive in controlling the ratio of total to available molybdenum as compared with their effect on the selenium ratio.

While the foregoing establishes the existence of a useful broad relationship between metal content of the drainage and the rocks, soils and herbage of the catchment area, detailed examination indicates a number of interesting features which undoubtedly reflect the modifying influence of geological, geochemical and biochemical factors. Work in progress is therefore primarily directed towards those aspects of the fundamental problem bearing on interpretation of the geochemical data, including: (1) the distribution and dispersion of molybdenum and selenium in both the bedrock and the zone of weathering; (2) the relative mobilities of those elements and the relationships between total and available metal; (3) the influence of relevant environmental factors, such as pH, Eh, drainage and soil type. Attention is also being given to the distribution of certain other constituents, notably copper, vanadium, phosphorus and sulphate.

Relationship between the geochemical patterns and animal health. Horses and cattle grazing herbage containing more than 5 p.p.m. selenium in the dried sample have shown symptoms of chronic selenium poisoning, including unthriftiness, loss of hair and abnormal growth of the hooves^{1,2,4}. At the known toxic locality A (Fig. 4) the maximum recorded value in the herbage is 100 p.p.m. selenium, while at B the content is 5–10 p.p.m. On the basis of a threshold level of 5 p.p.m.⁴, the results given in Fig. 4(c) point to the possibility of other suspect pastures in the immediate vicinity. Considering the region as a whole, four other toxic seleniferous localities are now known, all of which lie in the peak anomalous area indicated by the regional geochemical data (Fig. 2). Assuming similar sediment-plant relationships as exist in the detailed investigation area, other toxic localities—at the clinical or sub-clinical level—might be found elsewhere within the anomalous region where conditions of drainage and soil type are locally propitious for accumulation of selenium in a form available to the herbage.

Turning to molybdenum, some symptoms of molybdenum toxicity—notably fading of the coat and scouring—have been reported from Co. Limerick⁴. The provisional threshold level for toxic herbage is given as 5 p.p.m. in dry matter³, and soils with more than 10 p.p.m. total molybdenum are considered to be suspect⁴. On this basis, molybdenum toxicity or molybdenum-induced copper deficiency could exist in much of the western half of the detailed investigation area (Fig. 5). Again assuming comparable sediment-plant relationships in similar en-

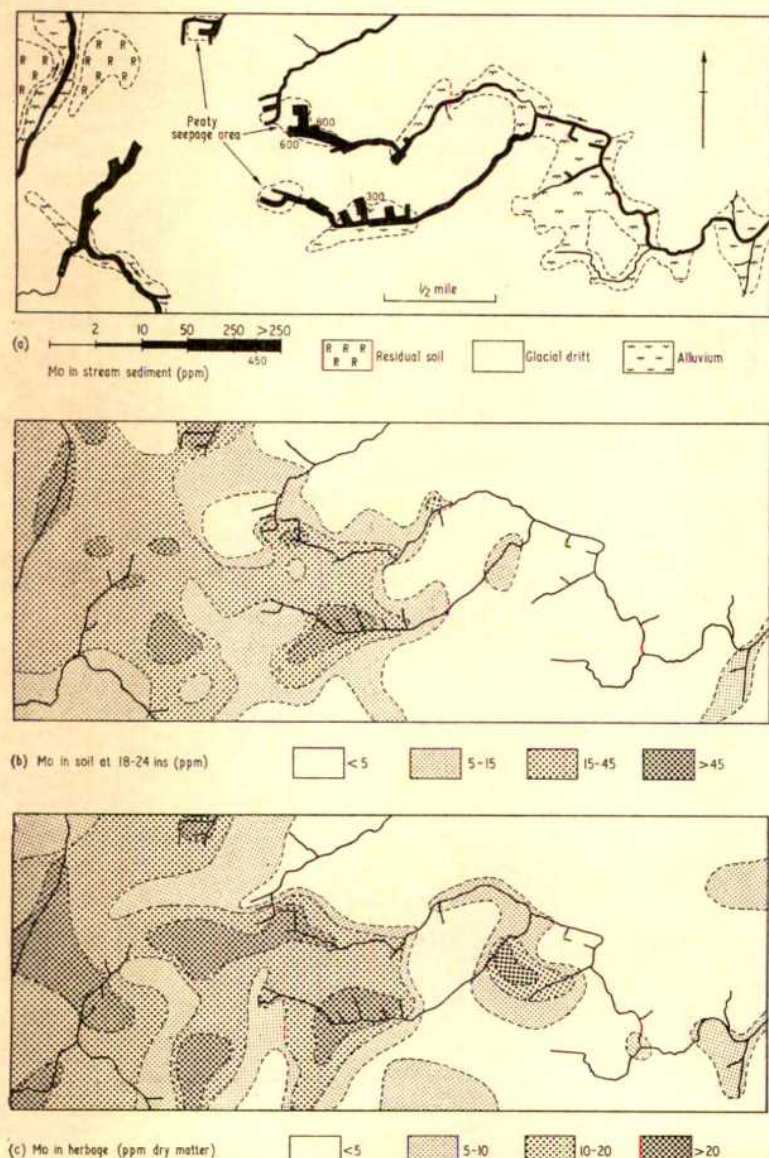

Fig. 5. Distribution of molybdenum in stream sediments, soil and mixed herbage (same samples as Fig. 4); simplified composition of the overburden (after O'Meara⁵) also shown in 5(a).

vironments in the region as a whole, the stream sediment pattern shown in Fig. 3 might well outline a considerable area wherein clinical or sub-clinical molybdenum toxicity (including molybdenum-induced copper deficiency) could be suspected. Since uptake of molybdenum from metal-rich soils appears to occur over a wider range of conditions than does selenium, excess molybdenum could well constitute the more extensive agricultural problem.

Conclusions. Though as yet incomplete, the results recorded here, taken in conjunction with earlier trials in Eire and the United Kingdom⁶, support the view that geochemical drainage reconnaissance has a useful part to play in the agricultural field. In this context, regional stream sediment surveys could provide an economical means of rapidly delineating suspect problem areas wherein to concentrate detailed investigation by more conventional methods not so well suited to regional application. Of considerable significance is the possibility that the data may also serve to outline areas of sub-clinical or latent¹¹ excesses or deficiencies, which can be the cause of great economic loss through sub-optimum yield or may only become apparent when the land is subjected to more intensive agriculture. On the research side, stream sediment surveys may provide a source of information concerning the regional distribution of a wide range of constituents of interest in the study of trace element interactions and nutritional imbalances in plants, animals and man.

Considerable work clearly remains to be done before the scope and limitations of the method can be fully appreciated. Nevertheless, there already seems good reason for believing that regional geochemical reconnaissance, properly used as an ancillary tool in conjunction

with geological, soil survey and other relevant techniques, can aid in agricultural appraisal and, possibly, eventually in epidemiology.

The fact that, with little additional effort, the same results may be used for mineral prospecting purposes could contribute a further incentive for undertaking regional geochemical surveys in appropriate areas.

We thank the Irish Agricultural Institute and the Irish Geological Survey for their advice. Considerable assistance was also given by our analytical colleagues, especially J. Henderson-Hamilton, Ann Cole, D. Williams and T. Forward.

The work forms part of the Department's continuing programme in applied biogeochemistry which latterly has been aided by a special research grant originally awarded by the Department of Scientific and Industrial Research and now received from the National Economic Research Council. One of us (W. J. A.) holds a Rio Tinto Zinc Corporation research bursary.

A NEW HAEMOGLOBIN, J TORONTO ($\alpha 5$ ALANINE \rightarrow ASPARTIC ACID)

By DR. J. H. CROOKSTON

Departments of Medicine and Pathology, University of Toronto, and the Toronto General Hospital, Toronto, Canada
AND

D. BEALE, D. IRVINE and DR. H. LEHMANN

Medical Research Council Abnormal Haemoglobin Research Unit, University Department of Biochemistry, Cambridge

DURING a deliberate search for abnormal haemoglobins among patients at the Toronto General Hospital, a 17-year-old girl of English ancestry was found to have a fast-moving abnormal haemoglobin band on electrophoresis at alkaline pH. The band was also present in the blood of her mother (Mrs. F. M.) (Fig. 1) but not in that of the mother's sister.

The mother was English, 48 years old, and in good health. Physical examination showed no abnormalities. Her haemoglobin level was 12 g/100 ml. with 2 per cent reticulocytes. The blood film showed very slight anisocytosis, but no target cells were seen. Incubation of a blood haemolysate at 48° C for 3 h with phosphate buffer, pH 7.2, failed to produce any precipitate. Incubation of her fresh red cells with acetylphenyl-hydrazine and with brilliant cresyl blue gave normal results.

An electrophoretically fast-moving haemoglobin was seen in the position of haemoglobin J, indicating that it carried one more negative charge per half molecule than haemoglobin A. The ratio of the haemoglobins A : J was 4 : 1. There were two haemoglobin A₂ fractions, one in the position of normal A₂ and another moving in front of it on paper and starch-gel electrophoresis at alkaline pH. The distance between the abnormal and the normal haemoglobin A₂ was the same as the distance between haemoglobin J and haemoglobin A. The 'double' haemoglobin A₂ suggested that the abnormality in the haemoglobin J resided in the α -chains, since haemoglobin A₂ possesses the same α -chains as haemoglobin A. An abnormality

Fig. 1. Paper electrophoresis (pH 8.9) of the haemoglobin of Mrs. F. M. (left) showing haemoglobin A, and a band moving in the position of haemoglobin J. On the right are haemoglobins A+J β Baltimore for comparison. Note that the concentration of the new haemoglobin J is not equal to that of A as it is in the haemoglobin A+J Baltimore sample.

of the α -chains in haemoglobin J ($\alpha^J\beta_2$) would be accompanied by an additional (abnormal) haemoglobin A₂ ($\alpha^J\delta_2$). Hybridization of the isolated haemoglobin J with canine haemoglobin, followed by electrophoresis at alkaline pH, showed that the β^J -subunits migrated like β^A , but the α^J -chains moved faster than α^A polypeptide chains. These findings confirmed that the haemoglobin was indeed a haemoglobin J α .

Examination of the amino-acid substitution. 'Fingerprints' of the haemoglobin J α , prepared according to Ingram¹ and Baglioni², were compared with those from haemoglobin A. References to these and other procedures involved have recently been listed³. They include the preparation of globin from haemoglobin, followed by tryptic digestion which splits the α -chain and the β -chain into small peptides wherever there are lysyl or arginyl bonds. These peptides are afterwards separated by electrophoresis in one direction (horizontal in Figs. 2 and 3) and then at right angles by chromatography (vertical in Figs. 2 and 3). This two-dimensional separation of the peptides results in a characteristic map of the peptides—the fingerprint. The peptides are numbered in the sequence in which they occur along α - and β -chains, respectively. α TpI (the α -chain's tryptic peptide No. 1) corresponds to residues α 1–7, and α TpII to residues 8–11 of the α -chain. Some free peptides α TpI and α TpII are formed on tryptic digestion, but the greater part of the sequence of residues 1–11 (the two peptides α TpI and α TpII) remains unhydrolysed under the conventional conditions of tryptic hydrolysis. The explanation is that

1	2	3	4	5	6	7	8	9	10	11
Val-Leu-Ser-Pro-Ala-Asp-Lys-Thr-Asn-Val-Lys										

Tryptic peptides α TpI (residues 1–7) and α TpII (residues 8–11) of the α -chain of haemoglobin A.
The arrow indicates where the two peptides are separated by tryptic hydrolysis. This separation is partially inhibited by the acidic aspartyl at position 6.

Table 2. AMINO-ACID ANALYSIS OF α TpI+II FROM HAEMOGLOBIN J AND HAEMOGLOBIN A

	Haemoglobin J μ moles	Residues	Haemoglobin A μ moles	Residues
Asp	0.222	3.1	0.221	2.1
Thr	0.077	1.1	0.114	1.1
Ser	0.075	1.0	0.117	1.1
Pro	0.079	1.1	0.124	1.2
Ala	0.007	< 0.1	0.122	1.2
Val	0.126	1.8	0.190	1.8
Leu	0.069	1.0	0.100	1.0
Lys	0.141	2.0	0.211	2.0

the acidic residue of aspartic acid in the position $\alpha 6$ inhibits the tryptic hydrolysis of the neighbouring bond of the basic lysine residue (Table 1).

Figs. 2 and 3 show peptide maps of haemoglobin A and haemoglobin J respectively. It will be seen that the spot representing α TpI+II in haemoglobin A is missing in the fingerprint of haemoglobin J. α TpI is also missing, but a faint spot representing α TpII is present. Two new spots are present in the fingerprint of haemoglobin J, one a neutral peptide close to β TpI, and another below β TpV (Figs. 2 and 3).

It was assumed that the more strongly staining spot in the neutral area represented the α TpI+II of haemoglobin J, and that the new acidic peptide was α TpI. These observations suggested a replacement of a neutral by an acidic residue in α TpI, a mutation which would result in a haemoglobin variant migrating electrophoretically as haemoglobin J.

To identify the amino-acid substitution, both α TpI+II and the presumed α TpI+II were separated by paper electrophoresis at pH 6.4 followed by chromatography for 24 h. At this stage the haemoglobin J peptide gave a positive staining reaction for histidine, indicating contamination by the histidyl-containing β TpI. Complete resolution from β TpI was obtained by a second electrophoresis at pH 6.4 with a potential gradient of 60 V/cm for 2 h.

Table 2 shows the results of the amino-acid analysis of α TpI+II and of the neutral peptide obtained from haemoglobin J. It will be seen that the haemoglobin J peptide contains all the amino-acids found after acid hydrolysis of α TpI+II except that alanine is missing and an additional aspartic acid is present. This finding suggests that the alanyl in position 5 of the α -chain of haemoglobin A has been replaced by a residue of aspartic acid and that this haemoglobin J is α_5^J Ala \rightarrow Asp β_2 . Such a variant has not been described before. It is proposed that this variant be named haemoglobin J α Toronto.

In the fingerprint of haemoglobin J Toronto the new faintly staining acidic peptide below β TpV almost certainly represented a trace of α TpI. However, because of the small amount present, attempts to isolate this peptide were unsuccessful.

Although no less than five mutations are known for the first peptide of the β -chain of human haemoglobin, none has previously been described for the α -chain (Table 3). It is thought that in human evolution the α -chain gave rise to the γ -chain and that

Fig. 2. Fingerprint of haemoglobin A. 1, α TpI (residues 1–7 of α -chain); 2, α TpII (residues 8–11); 3, α TpI+II

Fig. 3. Fingerprint of haemoglobin J α Toronto. 1, α TpI is missing; 2, α TpII is present but faint; 3, α TpI+II is missing; 4, a new peptide— α TpI; 5, a new peptide— α TpI+II

the β -chain arose afterwards from the γ -chain, and the δ -chain from the β -chain. It is of interest that the mutation α 5 Ala \rightarrow Asp in haemoglobin J Toronto represents a change, that is, from a neutral to an acidic residue similar to that (Ala \rightarrow Glu) which must have occurred in the non- α -chains (Table 4).

Twenty-seven types of amino-acid substitutions observed in human haemoglobins (including four differences between β - and δ -chains) have recently been summarized⁴. Since then the substitution Lys \rightarrow Gln has been observed in haemoglobin K Woolwich⁵; the present observation adds a

Table 3. β TpI and α TpI. A COMPARISON OF THE SUBSTITUTIONS KNOWN

						Lys	Lys

GLOBIN SYNTHESIS IN THALASSAEMIA: AN *IN VITRO* STUDY

By DR. D. J. WEATHERALL*, DR. J. B. CLEGG† and DR. M. A. NAUGHTON

Departments of Medicine and Biophysics, The John Hopkins University School of Medicine, Baltimore, Maryland

THE inherited haemoglobinopathies are of two main types. There are those, like sickle-cell disease, in which a structural change in one of the peptide chains of the globin fraction can be demonstrated, and there are others in which, despite evidence of an inherited defect in globin synthesis, no structural change in the globin moiety can be found. Disorders of haemoglobin synthesis of the second type are often found in patients with the clinical and haematological findings of thalassaemia and are, therefore, designated the 'thalassaemia syndromes'¹.

Human adult haemoglobin has a major and a minor component called haemoglobins A and A₂ respectively². Haemoglobin A has two α - and two β -peptide chains ($\alpha_2\beta_2$) and haemoglobin A₂ has two α - and two δ -chains ($\alpha_2\delta_2$) (ref. 3). Foetal haemoglobin, which has usually disappeared by the age of one year, has two α - and two γ -chains ($\alpha_2\gamma_2$) (ref. 4). There is good evidence that the structures of the α -, β -, γ -, and δ -chains are determined by separate pairs of genes⁵.

In some patients with the clinical picture of thalassaemia, foetal haemoglobin synthesis persists beyond the first year of life and haemoglobin A₂-levels exceed the normal range of 1.5–3.5 per cent of the total haemoglobin³. Furthermore, the genetic determinant for this type of thalassaemia behaves as though it were allelic or closely linked to the β -chain locus and also interacts with the sickle-cell (β^S -chain) gene⁶. These observations suggest that this form of thalassaemia results from an inherited defect in β -chain synthesis, the increased amounts of haemoglobins F and A₂ reflecting an attempt at compensation for the deficit in β -chains. The disorder is therefore designated β -thalassaemia.

Some patients with the clinical picture of thalassaemia do not have increased levels of haemoglobin A₂ and F, however, and the genetic determinant segregates separately from the β -chain gene⁶. Some, but not all, individuals in this group carry variable quantities of haemoglobins H and Bart's. Haemoglobin H is a tetramer of normal

β -chains (β_4), while haemoglobin Bart's is composed of four normal γ -chains (γ_4) (refs. 7, 8). It has been suggested, therefore, that this form of thalassaemia results from an inherited defect in α -chain synthesis, α -thalassaemia⁷, the resulting excess of β -chains or γ -chains aggregating to form haemoglobins H or Bart's respectively. This concept of the genetic basis of the thalassaemias, while serving as a useful model for their further investigation, is incomplete since there is increasing evidence for the existence of several types of β -thalassaemia and, probably, of α -thalassaemia¹.

Little is known about the mechanisms involved in the control of normal α - and β -chain synthesis in man, or about the factors which maintain δ -chain synthesis at about 1/40 of the level of β -chain synthesis. Furthermore, although there is evidence that the reticulocyte ribosomes of thalassaemic individuals have a reduced capacity for globin synthesis¹⁰, there has been no direct evidence for defective α - and β -chain synthesis in these disorders. The chemical structure of these chains appears to be normal¹¹ and the nature of the apparent defect in synthesis remains quite obscure. The experiments to be described here were carried out in an attempt to clarify some of these problems by comparing the *in vitro* incorporation of radioactive amino-acids into α -, β -, and δ -chains in the reticulocytes of thalassaemic and non-thalassaemic persons.

Reticulocyte-rich blood was obtained from 19 persons with the conditions listed in Tables 1, 2 and 3. 2–8 ml. of washed red cells was suspended in an amino-acid mixture¹² containing 25–100 μ c. of uniformly labelled ¹⁴C-leucine, and incubated in a Dubnoff metabolic shaker at 37° C, aliquots being removed at various times and immediately frozen. Haemoglobin fractions were purified by dialysis, column chromatography, and starch-block electrophoresis as previously described¹³.

In some experiments ribosomes were prepared¹⁴ before fractionation of the haemoglobins. Globin was prepared¹⁵ from either purified haemoglobin fractions or, in some cases, directly from the washed whole-cell lysates without further purification. The α - and β -chains were separated by gradient elution chromatography on carboxymethyl-

cellulose columns in urea/mercaptoethanol buffers as recently described¹⁶. In some experiments, chain separation was also achieved by hybridization with canine haemoglobin or by counter-current distribution¹⁷. The purity of each chain was checked by fingerprinting¹⁸ and the radioactivity measured, after plating out about 0.5 mg of protein on aluminium planchets, using a low-background gas-flow counter¹⁹. In order to determine the distribution of radioactivity in finished or partly finished chains on the ribosomes, 5–10 mg of unlabelled carrier globin was added to the ribosomal pellets and the α - and β -chains of the mixture separated by carboxymethyl-cellulose chromatography¹⁶.

Non-thalassaemic Reticulocytes

The specific activities of the separated α - and β -chains of purified haemoglobin A from a variety of non-thalassaemic conditions are summarized in Table 1 and the distribution of radioactivity in a typical chain separation, after 30 min incubation, is shown in Fig. 1. Under all conditions investigated the specific activities of the α - and β -chains were very similar at incubation times of 5 min to 5 h. At shorter times, however, the specific activity of the β -chain was always significantly greater than that of the α -chain. The pattern of radioactivity in separated α - and β -chains obtained from addition of carrier globin to ribosomal pellets was always the same in this group. Thus, the radioactivity under the α -chain peak always exceeded that under the β -chain peak, the ratio α -chain/ β -chain ranging from 1.5 to 2.1/1. Clear peaks of radioactivity were seen for both chains in each case, the radioactivity peak usually being slightly displaced from the

Fig. 1. Incorporation of radioactivity into the α - and β -chains of haemoglobin A prepared from the red cells of a patient with hereditary spherocytosis. Incubation period 45 min. ●—●, O.D. (0.280 μ); ○—○, radioactivity

protein peak. These results indicate that since the number of leucine residues in α - and β -chains is the same, α - and β -chain synthesis is normally synchronous. The fact that the specific activity of the β -chain is greater than that of the α -chain at short times of incubation, and the presence of an excess of radioactivity under the α -chain peak from the ribosomes after long periods of incubation, implies that a small pool of α -chain exists on the ribosomes. The existence of only a small peak of radioactivity associated with the β -chain from the ribosomes indicates that release of β -chains from the ribosomes is much more rapid than that of α -chains, but is not instantaneous. These observations suggest that finished β -chains are probably necessary for the removal of α -chains from the ribosomes. A similar situation has been described in the rabbit reticulocyte¹⁸ where the discrepancy in chromatographic behaviour between radioactivity (newly made chain) and carrier chain was also noted. Whether this means that the newly made chain, while still on the ribosome, is chemically different from that found in finished haemoglobin is not clear, but this would seem very likely.

In order to follow the incorporation of radioactive amino-acids into the α - and δ -chains of haemoglobin A₂, reticulocytes from an individual with hereditary spherocytosis were incubated with ¹⁴C-leucine for 60 min and haemoglobins A and A₂ isolated¹³. The α - and β -chains of haemoglobin A and the α - and δ -chains of haemoglobin A₂ were then separated and the specific activities of the whole haemoglobin fractions and separated chains determined (Table 3). As in previous experiments¹³ the specific activity of haemoglobin A was more than twice that of haemoglobin A₂. The specific activities of the α - and β -chains of haemoglobin A were very similar. The specific activity of the α -chain of haemoglobin A₂ was less than that of haemoglobin A—this finding being compatible with the finding¹³ that, in the *in vitro* system, haemoglobin A₂ synthesis in reticulocytes is retarded before that of haemoglobin A. This observation cannot, however, explain the ratio of specific activity of α -chain to δ -chain of 5/1 in haemoglobin A₂. It has recently been suggested that one reason for the relatively slow rate of δ -chain synthesis might lie in the presence of one or more 'slow points' during assembly of the δ -chain²⁰. In such an event, δ -chain clearance from the ribosomes would be slow relative to α -chain clearance. Thus, in investigations of radioactive incorporation, the time taken to achieve uniform δ -chain labelling would be longer than that required for uniform α -chain labelling, resulting in the marked difference in specific activity between α -chain and δ -chain observed in these experiments. These findings are thus compatible with the recent observation that uniform labelling of the δ -chain does in fact take a long period of incubation²⁰. Another explanation would be the exchange of α -chains between newly made haemoglobin A and haemoglobin A₂, the synthetic rate of which falls

off so rapidly in peripheral blood, but this mechanism seems very unlikely.

These results suggest, therefore, that there are 'slow points' in δ -chain synthesis giving rise to a relatively slow rate of clearance from the ribosomes. It is unlikely that the slow rate of δ -chain synthesis is associated with a quantitative reduction in messenger RNA since, although this would result in the production of fewer δ -chains, their specific activity would be similar to that of α -chains, if the rates of assembly of the two chains were comparable.

β -Thalassaemia Reticulocytes

The findings in the experiments utilizing cells from persons with β -thalassaemia, which were quite different from those in non-thalassaemic samples, are summarized in Table 2. The specific activity of the α -chain of purified haemoglobin A always exceeded that of the β -chain, the ratios α/β ranging from 1.5/1 to 7/1. These values were obtained at incubation times of 30 min–5 h, the differences being less marked after longer periods of incubation (Fig. 2). These ratios were similar to those recently reported¹⁰. In order to rule out the possibility of variation of leucine pool size for the two chains in this disorder, experiments were also performed with ^{14}C -lysine and ^{14}C -valine, similar differences in specific activity being noted. Such differences between the specific activities of the α - and β -chains in finished haemoglobin A could occur if a large intracellular pool of β -chain existed at any given time. After introduction of the radioisotope, newly made (and therefore labelled) β -chain would be diluted out by pre-existing unlabelled β -chains present in the pool. To examine this possibility, two experiments were carried out in which a chain separation was performed on a washed, whole-cell lysate without prior purification of haemoglobin fractions (Fig. 3). The recovery of protein and radioactivity exceeded 90 per cent in each case. Fingerprinting of each peak showed only α - and β -chain peptides, no new spots being observed. In both experiments the amount of radioactivity under the β -chain peak was similar to that found in the β -chain from purified haemoglobin A, which had been prepared from an equivalent amount of the original red-cell lysate. In one experiment a large peak of protein and radioactivity was eluted before the β -chain peak, this being the γ -chain of haemoglobin F, while in another too little haemoglobin F was present for clear separation of β - and γ -chains. These results thus excluded the presence of a large intracellular pool of β -chain, with subsequent dilution of newly labelled chains, as a basis for the observed differences in specific activity in α - and β -chains.

Such differences in specific activity could occur, however, if there were a large block (that is, rate-limiting step) at some point during the assembly of the β -chain or its release from the ribosome, associated with the presence on the ribosomes at any given time of many completed or

partially completed chains. As in the case of normal δ -chains already discussed, relatively long periods of time would then be required to achieve uniform labelling of newly synthesized β -chain. At long times, each newly synthesized chain would then have the same specific activity as an α -chain synthesized from the same amino-acid pool. The time required to achieve uniform labelling would thus depend on the severity of the block, that is, of the ease with which unlabelled β -chains present at the time of introduction of the radioactive amino-acid were cleared from the ribosomes.

One consequence of a rate-limiting step in synthesis, of the sort already discussed, would be the absence of radioactivity associated with β -chain on the ribosomes, in contrast to normal ribosomes where both labelled α - and β -chains can be shown to be present after a few minutes incubation (see earlier). Prolonged periods of incubation would be required to clear pre-existing unlabelled β -chains from the ribosomes and replace them with labelled chains. Ribosomes were therefore prepared from the red cells of two patients, homozygous for β -thalassaemia, after incubation of the cells with ^{14}C -leucine for 45 min. After addition of carrier globin to the ribosome pellet, the chains were separated by column chromatography. No peak of radioactivity corresponding to the β -chain was observed, while a large peak was seen in the α -chain region in each case (Fig. 4).

These findings are thus compatible with the concept of a gross defect in β -chain synthesis at the ribosomal level in β -thalassaemia. Whether, since α -chains appear to require finished β -chains for their release from the ribosomes, this results in a secondary accumulation of finished α -chain on the ribosomes is uncertain, although this seems likely since the relative amount of radioactivity in the α -chain fraction was several times that observed in

Fig. 3. Distribution of radioactivity compared with protein in a washed whole-cell lysate prepared from the red cells of a patient with β -thalassaemia major. Incubation time 60 min. \bullet — \bullet , O.D. (0.280 $m\mu$); \circ — \circ , radioactivity.

ribosomes obtained from non-thalassaemic reticulocytes. Further attempts to demonstrate the site of this proposed block in β -chain synthesis have been made by comparing the ratios of the specific activities of α - and β -chains of purified haemoglobin A prepared from four parallel incubations of aliquots of the same red cell sample using ^{14}C -labelled leucine, arginine, histidine, and tyrosine. Since these amino-acids are not distributed evenly along the peptide chain, the specific activities of non-uniformly labelled β -chains might be expected to differ with each amino-acid. The specific activities of individual peptides¹⁴ of thalassaemic β -chain were also measured. No definite site of delay in synthesis has yet been demonstrated, although the results have not excluded a 'slow point' either at, or near, the carboxyl-terminal end of the β -chain.

α -Thalassaemia (Haemoglobin H Disease) Reticulocytes

The results of six ^{14}C -leucine incubation experiments performed on the cells of persons with haemoglobin H thalassaemia are shown in Table 2. At incubation times of 30 min–5 h the specific activity of the α -chain of purified haemoglobin A was 1.5–15 times that of the β -chain (Fig. 5). This difference became less marked with more prolonged incubation of the red cells. Because of these findings, which were surprisingly like those in β -thalassaemia, the possibility of a large intracellular pool of β -chain diluting out newly made and, therefore, labelled β -chains again had to be examined. Washed whole-cell lysates from two persons with haemoglobin H disease were converted to globin without prior purification of the haemoglobins and the α - and β -chains separated (Fig. 6). The radioactivity in the β -chain fraction exceeded that in the α -chain fraction by a factor of 2.3/1 in one case and 3.0/1 in the second, while there was an associated increase in the optical density values for the β -chain peak. In a

separate experiment using identical amounts of the same two samples of washed whole-cell lysates, the amounts of haemoglobin A and H were determined and the radioactivity in each fraction measured. The excess of both radioactivity and optical density associated with the β -chain (over that present in the α -chain) of the whole-cell lysate could all be accounted for by the amount of protein and radioactivity found in the purified haemoglobin H fraction in the second experiment. Similar results were observed with ^{14}C -lysine. These results suggest that in haemoglobin H disease β -chain synthesis occurs at a rate of about 2–3 times that of α -chain synthesis, and that β -chains are freely released into the red cell where they form a large pool from which they are capable of uniting with newly made α -chains as these become available. When the cell is haemolysed, most of these β -chains appear in the haemoglobin H fraction. The presence of this large pool of β -chains at any one time probably explains the striking difference between the specific activities of the α - and β -chains of haemoglobin A in haemoglobin H disease. Newly-made labelled α -chains will combine with unlabelled β -chains which were already present in this pool. Whether the excess β -chains exist as haemoglobin H (β_4) in the red cell is uncertain, but at least in an *in vitro* system haemoglobin H readily combines with α -chains to form haemoglobin A²¹.

These experimental results must, of course, be interpreted with caution since the behaviour of cells in an *in vitro* system may not fully reflect their *in vivo* properties. Furthermore, this type of experiment utilizing peripheral blood only measures the last vestiges of protein synthesis in reticulocytes. However, certain tentative conclusions can be drawn. It appears that in non-thalassaemic individuals, α - and β -chain synthesis is synchronous and that, as previously suggested¹⁸, completed β -chains are required for the release of α -chains from the ribosomes. This probably results in a small number of finished α -chains being present on the ribosomes at any given time. Whether the peaks of radioactivity seen on ribosomal chain separations represent completed or partially completed chains is uncertain, although the high resolution of the chromatographic system used would have resulted in the separation of chains differing by as little as one charged residue¹⁸.

From the results of experiments on the kinetics of α - and δ -chain synthesis of haemoglobin A₂, it seems likely that at least one mechanism whereby δ -chain synthesis occurs at a slower rate than α - and β -chain synthesis is the slow ribosomal release of δ -chains. This slow release may well be due to the presence of one or more 'slow points' during assembly of the δ -chain.

In both forms of thalassaemia the specific activity of the α -chain of haemoglobin A exceeded that of the β -chain, even after long periods of cell incubation.

For α -thalassaemia, it has been clearly shown that α -chain synthesis occurs at about half the rate of β -chain synthesis, giving rise to a pool of free β -chain in the cell. Thus, although the rate of β -chain synthesis is greater than that of α -chain, the effect of the pre-existing pool of free β -chain is to dilute newly synthesized labelled β -chains. The specific activity of the β -chain is thus considerably lower than that of the α -chain even though synthesis of the latter is impaired.

In β -thalassaemia, no such pool of β -chains could be demonstrated, nor was a large pool of free α -chain detected. However, excess α -chains do occur. Some are bound to γ -chain (as haemoglobin F), others appear to be attached to ribosomes, and some excess α -chain has been observed in chain separations of globin prepared from red cell stroma. These observations are in keeping with the suggestion²² that excess α -chain may be insoluble and precipitates in the cell to form the inclusion bodies characteristic of β -thalassaemia.

Fig. 5. Distribution of radioactivity in the α - and β -chains of haemoglobin A from the cells of a patient with haemoglobin H disease. Incubation time 45 min. ●—●, O.D. (0.280 μ); ○---○, radioactivity

Fig. 6. Distribution of radioactivity compared with protein in a washed whole cell lysate prepared from the red cells of a patient with haemoglobin H disease. Incubation time 45 min. ●—●, O.D. (0.280 μ); ○---○, radioactivity

From the data presented, the most probable explanation of the marked difference of specific activity between α - and β -chains in β -thalassaemia is a block or 'slow point' during the assembly of the β -chain, resulting in an accumulation of completed or partially completed β -chains on the ribosomes. It seems likely that since α -chains require β -chains for their release, there is also a secondary accumulation of α -chains on the ribosomes. It is difficult to imagine a mechanism which could give rise to the differences in the specific activities of the α - and β -chains noted here, and yet at the same time leave the rate of assembly of the β -chain unaltered. If, for example, the defect were simply in the number of ribosomes active in β -chain synthesis, there would be a deficit in β -chains but those which were made would have the same specific activity as α -chains. Similarly, a net reduction of messenger RNA for β -chains would lead to a deficit in β -chains, but would not be expected to give rise to different specific activities of the α - and β -chains in completed haemoglobin A unless the rates of assembly of the two chains were also different. Experiments using multiple ^{14}C -labelled amino-acids have tentatively ruled out the N-terminal and central region of the chain as a site of a block in synthesis, but it could occur at or near the carboxyl-terminal end of the molecule. Whichever is true, it seems quite probable that in different instances of β -thalassaemia the site of the defect may not always be the same. The heterogeneity of β -thalassaemias already recognized¹ may be, in some part, a reflexion of this. The similarity of the kinetics of peptide chain synthesis in thalassaemic β -chains and the δ -chains of normal haemoglobin A₂ suggests that a rewarding approach to the β -thalassaemia problem might be in the search for rate-limiting steps in synthesis. A reduction in the rate of α -chain synthesis in haemoglobin H disease has been shown and a similar search for the presence of 'slow points' in α -chain synthesis in this disorder is indicated.

In the absence of evidence indicating structural changes in the α - and β -chains of haemoglobin A in thalassaemia, it seems likely that explanations for these disorders may be found in changes in one or more of the factors which affect the process of assembly of the protein on the ribosomes. Mutations leading to changes in messenger RNA codewords, for example, while producing no change in the sequence of amino-acids, might, nevertheless, alter the rates of translation by requiring recognition of the altered codons by other sRNA anti-codons. It is conceivable that if synthesis of the α - or β -chains is dependent on a polycistronic messenger RNA, then changes in messenger RNA at a site remote from the α - or β -chain cistron might in some way influence the rate of assembly

or the α - or β -peptide chain²³. However, this mechanism seems less probable than one directly involving the α - or β -chain messenger RNA. Alternatively, it is possible that mutations leading to changes in specific sRNAs or ribosomal RNA could also influence the rate of assembly of one peptide chain relative to another. An instance where a leucine-specific sRNA is involved in the coding of only one out of some 30 leucine residues in the rabbit haemoglobin molecule is already known²⁴. The recent advances in the techniques for isolating and studying messenger RNA and sRNA from mammalian cells may eventually provide the necessary means of investigating the problem at this level.

We thank Dr. Marion Erlandson and Dr. Carl Smith for their help in obtaining blood samples for these investigations. We also thank Dr. S. H. Boyer, Dr. C. L. Conley, Dr. H. M. Dintzis and Dr. G. Von Ehrenstein for their advice.

PROMOTION BY KINETIN OF THE POLAR TRANSPORT OF TWO AUXINS

By DR. C. C. MCCREADY, DR. DAPHNE J. OSBORNE and M. KAY BLACK*

Agricultural Research Council Unit of Experimental Agronomy, Department of Agriculture, University of Oxford

IN higher plants, auxin is synthesized chiefly in certain limited regions. The amounts of auxin reaching cells remote from these regions must depend in part on the ability of the intervening tissues to transport auxin. At present, little is known of the ways in which the movement of auxin is regulated. We describe here experiments on the transport of a natural and a synthetic auxin through segments cut from bean petioles. In both cases auxin transport was greatly enhanced by treatment of the segments with a growth regulator of another type, the cytokinin¹ kinetin (6-furfurylaminopurine). This effect was best observed in segments which had been excised from the plant some time before the measurement of auxin transport was begun.

Seedlings of *Phaseolus vulgaris*, var. Canadian Wonder, were raised in a greenhouse and used when the petioles of the young primary leaves were elongating rapidly. Each experiment was conducted in two stages. Segments cut from these petioles were first treated either with kinetin or with water, as described in detail later. Afterwards the basipetal movement of each auxin through the segments was determined by the following method, which in principle resembles that of Went². A donor block of 1.5 per cent agar gel, 23 μl . in volume, incorporating the auxin labelled with carbon-14, was applied to the distal end of each segment. A receiver block of plain agar gel was at once applied to the proximal end of the segment, and transport was allowed to proceed at $25^\circ \pm 0.5^\circ \text{C}$ in a humid atmosphere in darkness. After a suitable interval the donor and the receiver blocks were removed and

* Permanent address: Department of Biochemistry, University of California, Riverside, California.

assayed for carbon-14. Standard sets of unused donor blocks were similarly assayed. All results were corrected for background. The materials and methods used have been more fully described by McCready³. To indicate the effect of kinetin on the transport of carbon-14, the counts per minute (c.p.m.) in receivers from kinetin-treated segments are shown in Tables 1-3 as a percentage of the c.p.m. in receivers from control segments which had been treated with water instead of kinetin. The auxins used were indolyl-3-acetic acid-methylene-¹⁴C (IAA) and 2,4,5-trichlorophenoxyacetic acid-carboxyl-¹⁴C (2,4,5-T). The latter was chosen because in these segments it is transported with high polarity in larger amounts than IAA and is less subject to breakdown (McCready, unpublished results).

In experiments designed to compare freshly excised tissue with aged tissue, treatments were applied in the following ways. If the tissue was to be used fresh, a segment 5.4 mm in length was cut from the middle of the petiole of each of the paired primary leaves of a seedling. The segments were laid horizontally on grooved racks which left their ends free. One segment of each pair was at once treated with kinetin, 1 μ l. of a 233 μ M solution being placed on each cut end with a micrometer syringe. One

μ l. of water was similarly applied to each end of the segment from the opposite petiole, which served as a control. After this treatment the segments were left in a humid atmosphere in darkness at 25° C for 40-45 min to allow absorption of the droplets before donor and receiver blocks were applied.

If the tissue was to be used after a period of ageing, segments 8.0 mm in length were cut and laid on racks in the same way. Kinetin was applied to some segments before ageing, and to others after ageing. In either case, the segments and their paired controls were stored for 13 or 20 h in the conditions already described. From the middle of each 8-mm segment a 5.4-mm portion was then cut, and donor and receiver blocks were applied to its ends for the measurement of transport. Unless the agar blocks were applied to surfaces freshly cut in this way, auxin transport through stored segments was much reduced, especially with IAA. This reduction was probably due in part to a gradual distortion of the ends of the segments during storage which prevented proper contact between tissue and blocks, and in part to the development of IAA-destroying enzymes at the exposed cut surfaces.

Table 1 shows the results of an experiment in which the transport of IAA was measured with and without kinetin, the treatment being applied in three different ways to segments cut from the same batch of plants. In the first type of treatment, fresh 5.4-mm segments were treated with kinetin or with water and left for 40-45 min, after which auxin transport was measured over a period of 4 h. Kinetin had no effect on the amount of carbon-14 appearing in the receiver blocks. In the second type of treatment, 8-mm segments were treated with kinetin or water and stored for 20 h. The segments were then cut to 5.4 mm, 1 μ l. of water was added to each end, and after 40-60 min transport was measured as before. In the receivers from stored control segments which had been given no kinetin, only 1/5-1/3 as much carbon-14 appeared as in receivers from fresh control segments. However, the stored tissue which had been treated with kinetin transported about 1.7 times as much carbon-14 as the stored controls. Although transport through the segments treated before storage was still only about half that through fresh segments, the effect of kinetin on transport through the stored tissue was clearly substantial.

The fact that kinetin enhanced the transport of auxin only in the stored segments suggested a possible explanation of its mode of action. It has been reported that kinetin retards or prevents some of the changes typical of ageing in detached leaves⁴⁻⁶. To test whether its function here was of a similar nature, the third type of treatment was included: 8-mm segments were treated with water alone, stored for 20 h, cut to a length of 5.4 mm and then given kinetin or water 20-45 min before auxin transport began. Kinetin applied in this way, after the ageing period, was just as effective in promoting auxin transport as kinetin applied before ageing. It was therefore concluded that the action of kinetin was not simply to retard the fall in the ability of the segments to transport auxin. After the transport capacity of the tissues had fallen during storage without kinetin, they responded to kinetin by increased auxin transport. In the stored segments some change had occurred which caused auxin transport to become sensitive to kinetin.

Table 2 shows the results of an experiment, similar in principle, in which 2,4,5-T was the auxin transported. Only the timing was altered, to allow for the fact that 2,4,5-T, like 2,4-dichlorophenoxyacetic acid^{3,7}, moves with a much lower velocity than IAA. It was therefore convenient to measure 2,4,5-T transport over a longer period, in this case 12 h. To avoid using excessively old tissues, the period of storage was reduced to 13 h. In stored segments kinetin caused an even larger promotion of the transport of 2,4,5-T than of IAA and again it was immaterial whether kinetin was applied before or after the period of storage. A small effect was seen even with

Table 1. BASIPETAL TRANSPORT OF INDOLYL-3-ACETIC ACID-¹⁴C (IAA) THROUGH PETIOLE SEGMENTS OF *P. vulgaris* WITH OR WITHOUT KINETIN

Pretreatment	C.p.m. from receivers		+ Kinetin - Kinetin Duplicates	$\times 100$ Mean
	- Kinetin	+ Kinetin

Pretreatments: 1 μ l. kinetin, 233 μ M, or water to each end of segment (for details see text). Initial concentration of 2,4,5-T in donors: 5 μ M. Initial radioactivity in donors: 2,362 c.p.m. Transport 12 h through 5.4 mm segments. Duplicate treatments, 11 segments in each.

Table 3. CHROMATOGRAPHY OF EXTRACTS FROM RECEIVERS AFTER BASIPETAL TRANSPORT OF ¹⁴C-LABELLED AUXINS THROUGH PETIOLE SEGMENTS OF *P. vulgaris* STORED WITH OR WITHOUT KINETIN

Auxin:		Indolyl-3-acetic acid (IAA)		2,4,5-Trichlorophenoxyacetic acid (2,4,5-T)	
C.p.m. from receivers, + kinetin/-kinetin $\times 100$:					
Duplicates	Mean	280	244	141	143
		262		142	
Chromatographic solvent:		Acid		Alkaline	
R_F of auxin zone:		0.75-0.90		0.20-0.35	
C.p.m. from auxin zone as percentage of total c.p.m. from chromatogram:		Acid		Alkaline	
		0.75-0.90		0.55-0.70	
- Kinetin		76		88	
+ Kinetin		80		87	

Pretreatments: 1 μ l. kinetin, 233 μ M, or water to each end of segment. For IAA, 10.5 mm segments \pm kinetin were stored for 14-16 h at 25° C. For 2,4,5-T, 10.5 mm segments \pm kinetin were stored for 14-16 h at 20° C. All segments were cut to 5.4 mm for transport. Initial concentration of IAA in donors: 20 μ M. Initial radioactivity in donors: 8,914 c.p.m. Transport 5 h. 16 segments per treatment for assay, 92 for chromatography. Initial concentration of 2,4,5-T in donors: 20 μ M. Initial radioactivity in donors: 3,678 c.p.m. Transport 14 h. 16 segments per treatment for assay, 94 for chromatography. For chromatographic solvents see text.

fresh tissue, perhaps because the duration of the transport experiment was long enough to allow the development of some sensitivity to kinetin.

We next considered the possibility that in these experiments kinetin was promoting not the transport of the auxins themselves but the production or movement of labelled metabolites formed from them. It seemed unlikely that this could be the explanation of such similar effects on two chemically dissimilar auxins, labelled in positions which were not analogous. Nevertheless, the suggestion was tested by examining chromatographically the labelled substances extracted from receiver blocks. Transport experiments were set up with each auxin using segments from tissue pretreated with kinetin or water as previously described and later stored as shown in Table 3. At the end of the transport period, duplicate sets of receivers from both treated and control segments were assayed for carbon-14 to estimate the magnitude of the kinetin effect. The remaining treated and control receivers were extracted three times with ether slightly acidified with acetic acid (0.05 per cent v/v for IAA, 0.2 per cent for 2,4,5-T). Samples of 16 receivers assayed after extraction contained 15–17 per cent (IAA) or 0.5–1.1 per cent (2,4,5-T) of the carbon-14 in receivers assayed before extraction. Each extract was concentrated to a small volume in a stream of nitrogen and spotted on to two paper strips for development by ascending chromatography, one in an acid solvent (*n*-butanol/acetic acid/water, 5:2:2 v/v) and the other in an alkaline solvent (isopropanol/ammonia/water, 10:1:1 v/v). These and similar solvents have been widely used for the separation of metabolites of both IAA and chloro-substituted phenoxyacetic acids. After running for 10 h each chromatogram was dried and divided into 20 sections equal in size except for that next to the origin, which was extended by 5 mm to include the whole area of the initial spot. The sections were assayed for carbon-14 by means of a liquid scintillation counter⁸.

In Table 3 the c.p.m. from a zone 0.15 R_F units in extent including the auxin peak are shown as a percentage of the total c.p.m. from each chromatogram. When extracts of receivers from kinetin-treated and control segments were compared, the proportion of the carbon-14 appearing in the auxin peak in the two cases never differed by more than 4 per cent of the total on the chromatogram. Therefore the greater radioactivity of the receivers from kinetin-treated tissue—262 per cent of the controls with IAA, 142 per cent with 2,4,5-T—could not to any important extent be due to an increase in the proportion of the carbon-14 found in substances separable from the auxins by chromatography in the two solvents used.

We conclude that when segments of *Phaseolus* petioles are stored as described, those treated with kinetin later transport auxins in markedly larger amounts than do controls. Although the promotion of auxin transport was reproducible within each experiment, as may be seen from the agreement of duplicate treatments, the magnitude of the effect differed from occasion to occasion. We attribute this variability to differences between successive batches of our plants, which were not grown in rigidly controlled conditions. Nevertheless in every one of our series of 34 experiments, some of which are to be reported in another communication, kinetin increased auxin transport.

The amount of auxin entering the segments was estimated from the difference in carbon-14 content between unused donor blocks and donors removed at the end of an experiment. The effects of kinetin on auxin uptake were small and variable but usually positive. In the great majority of cases—111 out of 128 individual treatments—kinetin caused an increase in the amount of carbon-14 entering the receivers which was greater than any increase in the amount leaving the corresponding donors. It follows that the increased transport into the receivers from treated segments could not have been caused solely by a promotion of uptake by kinetin. Indeed, any increase in uptake could

have been simply a consequence of increased transport of auxin away from the distal ends of the kinetin-treated segments.

Mothes, Engelbrecht and Kulajewa⁵ have described and others have confirmed⁹ a "directed transport" of various metabolites into kinetin-treated areas of the laminae of detached leaves. Conrad¹⁰ has reported a similar effect of local applications of kinetin on the distribution of both endogenous auxin and applied IAA in the laminae of detached leaves of *Brassica napus*. Auxin was accumulated and apparently retained in the treated areas. This phenomenon seems to be quite distinct from that revealed by our experiments, in which an increase occurred, not in the amounts of auxins accumulated in the kinetin-treated petiole segments, but in the amounts transported through and out of them.

The difference in response to added kinetin between fresh and aged segments may be simply explained by the hypothesis that the polar transport of auxin can proceed at its maximum rate only in the presence of a sufficient concentration of a cytokinin. It may be supposed that fresh tissue initially contains adequate supplies of an endogenous cytokinin but that this is so depleted during storage of the segments that lack of it becomes a limiting factor for auxin transport. Added kinetin can then to some extent substitute for the natural cytokinin and partly restore auxin transport. The persistence of the effect of kinetin applied to segments before storage is probably due to the use in the present experiments of amounts which were later found to be greatly in excess of the level which sufficed to produce the maximum response.

It has recently been shown^{11,12} that another synthetic cytokinin, *N*₆-benzyladenine, is itself transported in a polar fashion through segments of *Phaseolus* petioles. If the supposed endogenous cytokinin moves similarly, its depletion in the stored segments might well be the result of basipetal movement out of the parts of the segments later used for the measurement of auxin transport.

We end with a speculation. It has been reported elsewhere^{11,12} that the transport of benzyladenine is greatly increased by IAA. The experiments described here show that IAA transport is markedly increased by kinetin, and Black and Osborne¹² find that benzyladenine has a similar effect. It is well established that the balance between kinetin and IAA can profoundly affect plant growth: see, for example, the discussions by Miller¹³ and Setterfield¹⁴. It seems reasonable to suppose that in the intact plant an endogenous cytokinin may behave similarly to kinetin and benzyladenine in all these ways. If so, the mutual promotion of cytokinin and auxin transport might serve to control the ratio of the amounts of the two substances reaching a particular tissue from regions of synthesis elsewhere. The interdependent transport of the two hormones would then constitute a regulatory mechanism of a novel kind.

We thank Prof. G. E. Blackman for advice, Mr. R. G. Powell for preparing the radioactive solutions and for much helpful discussion, and Dr. M. A. Foster for the use of a liquid scintillation counter.

ENZYMATIC ADAPTATION TO CONTRACTILE ACTIVITY IN SKELETAL MUSCLE

By J. KENDRICK-JONES and PROF. S. V. PERRY

Department of Biochemistry, University of Birmingham

IF skeletal muscle is made to contract in a regular and repeated fashion in excess of normal use, as in training, the tissue appears to adapt to the increased activity by improved performance and often marked hypertrophy. Nevertheless, attempts to relate the marked changes in performance brought about by exercise to persistent biochemical changes in the skeletal muscle cell have led to somewhat contradictory results.

There is some evidence¹ that exercise can increase the size and number of myofibrils in the sartorius muscle of the rat, an observation which would correlate well with Helander's² finding that exercise increases, and restriction in activity decreases, the proportion of myofibrillar to sarcoplasmic protein.

Unequivocal demonstrations of appreciable changes in the activity of skeletal muscle enzymes as a result of exercise which are widely accepted by all workers are hard to find. Lawrie³ has, however, reported an increase in the myoglobin content of the muscles of rats subjected to strenuous daily exercise for an extended period. So far as can be determined by a search of the literature no *in vitro* investigations of enzymatic adaptation to muscle activity have been published.

Much of the early work on the biochemical adaptation of muscle to activity was carried out by Russian workers⁴, who reported increases in α -glycerophosphate dehydrogenase, hexokinase, lactic dehydrogenase and succinic dehydrogenase in both heart and skeletal muscle of rats subjected to a programme of regular strenuous exercise. Yakovlev⁵ has also claimed that exercise increases the myosin ATPase activity by increasing the content of thiol groups which bind ATP. More recent investigations have failed to confirm increases in succinic⁶ and lactic dehydrogenases^{7,8} and have indicated that the levels of aldolase⁹, malic dehydrogenase⁸, phosphorylase, creatine phosphokinase⁸, and calcium-activated adenosine triphosphatase^{8,10} do not increase, when related to total nitrogen or to non-collagen protein nitrogen, in skeletal muscle after exercise. Hearn and Gollnick^{7,10} have, however, reported increases of a few per cent in the activity of heart-ventricle lactic dehydrogenase and adenosine triphosphatase after exercise, although the activity of the skeletal muscle enzymes of the same animals were unchanged. Apart from the early Russian reports, work of most investigators suggests, in the main, that after long or short periods of exercise little change can be demonstrated in the specific activities of the muscle enzymes.

Our interest in this problem arose out of an investigation of the biochemical changes occurring during development in skeletal muscle and the finding¹¹ that in several species there was a good correlation between the onset of regular use of a skeletal muscle and the rapid increases in the specific activities of creatine phosphokinase and 5'-adenylyc deaminase which occur in early neonatal life. The findings suggested that the rise in activity of these enzymes was closely associated with increased contractile function. In the case of the new-born rabbit it was possible to bring forward by several days the increase in creatine phosphokinase in the thigh muscles of the back legs by encouraging the young rabbit to move about earlier than was normal by disturbing the mother's nest. Similar although less clear-cut results were obtained with 5'-adenylyc deaminase. The latter findings are in line with evidence¹² for the adaptive formation of this enzyme

in skeletal muscle of the rat exercised in the Noble-Collip drum, briefly reported by Ninomya *et al.*¹², the results of which we became aware after this work was completed.

Extension of the findings with young rabbits to other species showed that exercising young rats in a treadmill for relatively short periods (4–24 h) produced a significant increase in the creatine phosphokinase-levels of leg muscles compared with controls permitted normal or restricted activity. Some of the results obtained are summarized in Table 1 where the enzymatic activity is related to the total protein nitrogen, extracted under a procedure (Table 1) which removed all the enzyme from the tissue. The values can be directly related to the wet weight or the total nitrogen content of whole muscle, as control experiments showed that the procedure extracted a constant fraction of the total nitrogen of the muscle and that this fraction was not changed by exercise. It is significant that the percentage increases in specific activity obtained were often more marked if the animal was restricted in activity for a period before the experimental period.

In the case of restricted controls the creatine phosphokinase-levels fell to lower values than those found in the same muscles of litter-mate controls permitted normal activity. The results suggested that the creatine phosphokinase level is maintained at fairly high values by normal use of the muscles and only when the use is restricted appreciably does the enzymatic level fall. In these cases a subsequent period of intense activity caused a marked increase in creatine phosphokinase activity. The failure of other workers to demonstrate increases in enzymatic activity after exercise may, in part, have been due to the fact that the activity of muscles of the control animals was sufficiently great to maintain the creatine phosphokinase at an adequate level which was not readily increased by further exercise. The age of the experimental animals may also be important in so far as the ability of skeletal muscle to adapt is probably more highly developed in young animals.

Similar significant increases in aldolase and myokinase¹⁴ activity were also found in homogenates of whole flight muscle of the desert locust, *Schistocerca gregaria*, made to fly in a current of air by the method of Weis-Fogh¹⁵ for six periods of 30 min, each period interspersed with 30 min rest. These locusts, which had been reared from the larval stage in captivity, had not previously flown. Creatine phosphokinase and 5'-adenylyc deaminase could not be detected in these muscles.

As all the foregoing results were obtained *in vitro*, it was difficult to decide whether the response in enzymatic levels was controlled entirely by intracellular mechanisms or was a response to a more systemic stimulus. The endogenous nature of the response was indicated in experiments with the isolated sartorius of *Rana temporaria*.

In these experiments isotonic twitches were elicited once every 8 sec by stimuli of supramaximal intensity using electrodes placed close to the muscle and immersed in oxygenated Ringer. The twitches were recorded with a simple unloaded lever-drum kymograph system and the corresponding unstimulated muscle from the other limb of the same frog was stretched to a similar rest length either alongside the contracting muscle in the same bath, or, in some experiments, in a separate identical chamber.

Table 1. EFFECT OF EXERCISE ON THE CREATINE PHOSPHOKINASE AND ALDOLASE ACTIVITIES OF RAT HIND-LEG MUSCLE

Exp. No.		Age (days)	Body-wt. (g)	Creatine phosphokinase (μ g creatine/mg N of extract/min)	Aldolase (μ g triose P/mg N of extract/15 min)
